SUBSTANTIATION: Ground-Fault Circuit Protection of subdivided circuits in large pool and spa water heaters is without justification. Heaters of this size are not installed by homeowners but are installed, grounded and bonded by licensed electricians. Coates Heater Co., Inc. is not aware of any shock injury to a swimmer or spa/hot-tub user caused by one of its pool and spa water heaters. GFCI protection for these heaters will cause an estimated increase up to double the cost to the consumer. Some heaters could require as many as 12 individual GFCI units making installation cumbersome and prohibitively expensive; legislating the residential electric pool and spa heater out of business. A field assembled spa or hot-tub is different than a selfcontained or packaged unit. It is very similar to a swimming pool.
PANEL ACTION: Accept in Principle.
In proposal 20-30a Section 680-44(B) is to be deleted and renumber (C) to (B) and (D) to (C).
Add text in renumbered Section 680-44(B) to read as follows: "(B) Other Units. A field assembled spa or hot tub rated 3 phase or rated over 250 volts or with a heater load of more than 50 amperes shall not require the supply to be protected by a ground-fault circuit interrupter."
PANEL STATEMENT: It is the panel intention to retain the editorial rewrite of Proposal 20-30a without changing the requirements of the 1999 NEC.

VOTE ON PANEL ACTION:
AFFIRMATIVE: 11

(Log #1985)

20- 35 - (680-51): Hold
SUBMITTER: Robert E. Wisenburg, Coates Heater Co., Inc./Rep. National Spa & Pool Institute
COMMENT ON PROPOSAL NO: 20-30a
RECOMMENDATION: Revise text as follows:
(A) Ground-Fault Circuit Interrupters. Fountain equipment unless listed for operation at 15 volts or less and supplied by a transformer that complies with 680.25(A)(2), shall be protected by a ground-fault circuit interrupter except as noted.
Electric heaters used for freeze protection shall meet the requirements of 680.9 and 680.26(E).
SUBSTANTIATION: Electric swimming pool heaters are often used to provide freeze protection for fountains. These heaters may be as large as 100 kW or more and are most often three phase and may be 480 volt. GFCI protection is not available for these units and they should be treated like swimming pool heaters.
PANEL ACTION: Hold.
PANEL STATEMENT: The submitter has introduced new material and the panel has placed this comment on hold until the next code cycle in accordance with Regulation Governing Committee Projects Section 4-4.6.2.2
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 11
VOTE ON PANEL ACTION:

20- 36 - (680-56(b)): Accept
SUBMITTER: Larry F. Miller, National Electrical Manufacturers Association (NEMA)
COMMENT ON PROPOSAL NO: 20-129a
RECOMMENDATION: The Panel should Accept n Principal in Part and revise 680-56(b) to read:
(b) Cord Type. Flexible cord immersed in or exposed to water shall be of a type for extra hard usage, as designated in Table 400-4, and shall be a listed type with a "W" suffix.
SUBSTANTIATION: The "W" suffix is the proper designator for water resistant cords. "Marked for the purpose" is ambiguous.
PANEL ACTION: Accept.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 11
VOTE ON PANEL ACTION:
AFFIRMATIVE: 11

(Log #1987)

20- 37 - (680-62(a)(2)): Accept in Principle
SUBMITTER: Robert E. Wisenburg, Coates Heater Co., Inc./Rep. National Spa & Pool Institute
COMMENT ON PROPOSAL NO: 20-30a
RECOMMENDATION: Delete subdivided loads. Return to the wording of 680-62(a) in the 1999 National Electrical Code.
SUBSTANTIATION: Ground-Fault Circuit Protection of subdivided circuits in large pool and spa water heaters is without justification. Heaters of this size are not installed by homeowners but are installed, grounded and bonded by licensed electricians. Coates Heater Co., Inc. is not aware of any shock injury to a swimmer or spa/hot-tub user caused by one of its pool and spa water heaters. GFCI protection for these heaters will cause an estimated increase up to double the cost to the purchaser. Some heaters could require as many as 12 individual GFCI units making installation cumbersome and prohibitively expensive. A field assembled Therapeutic pool and tubs is different then a selfcontained or packaged unit. It is very similar to a swimming pool.
PANEL ACTION: Accept in Principle.
In proposal 20-30a delete Section 680-62(A)(2) and renumber Section 680-62(A)(3) to be Section 680- 62(A)(2).
Add text in renumbered Section 680-62(A)(2) to read as follows:"(2) Other Units. A therapeutic tub or hydrotherapeutic tank rated 3 phase or rated over 250 volts or with a heater load of more than 50 amperes shall not require the supply to be protected by a ground-fault circuit interrupter."
PANEL STATEMENT: It is the panel intention to retain the editorial rewrite of Proposal 20-30a without changing the requirements of the 1999 NEC.

ARTICLE 690 — SOLAR PHOTOVOLTAIC SYSTEMS

(Log #979)

3- 85 - (Figure 690-1): Accept in Principle
Note: The Technical Correlating Committee directs that the first sentence of the Panel Action text be moved into the Panel Statement.
SUBMITTER: John C. Wiles, Jr., Southwest Tech. Development Inst.
COMMENT ON PROPOSAL NO: 3-144
RECOMMENDATION: In the Draft of Proposed NFPA 70, 2002 Edition, National Electrical Code, the diode symbols have not been revised per the original submission.
SUBSTANTIATION: None.
PANEL ACTION: Accept in Principle.
The comment does not comply with the requirement of Section 4-4.5(c) of the NFPA Regulations Governing Committee Projects by including the proposed revision. NFPA Staff should verify the symbol is correct by using the IEEE symbol for a diode. The symbol in the NEC Draft needs to be further revised to reflect the recognized symbol for a diode with the base triangle being as wide as the bar on the top.
PANEL STATEMENT: The panel action meets the intent of the submitter and clarifies the diagram symbol.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 12
VOTE ON PANEL ACTION:

3- 86 - (690-2-System Voltage, Photovoltaic Systems Voltage (New)): Accept
SUBMITTER: Technical Correlating Committee National Electrical Code
COMMENT ON PROPOSAL NO: 3-149
RECOMMENDATION: The Technical Correlating Committee directs the Panel to revise the definition to remove the requirement in accordance with the NEC Style Manual. This action will be considered by the Panel as a Public Comment.
SUBSTANTIATION: This is a direction from the National Electrical Code Technical Correlating Committee in accordance with 3-4.2 and 3-4.3 of the Regulations Governing Committee Projects.
PANEL ACTION: Accept.
Accept the direction of the Technical Correlating Committee and change the definition to read as follows:
Photovoltaic Systems Voltage. The direct current (dc) voltage of

any photovoltaic source or photovoltaic output circuit. For bipolar or multiwire installations, the photovoltaic systems voltage is the highest voltage between any two dc conductors.
PANEL STATEMENT: By removing the phrase "shall be" and replacing it with the word "is", the panel has removed the requirement aspect of the definition while retaining the definition in its entirety.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 12
VOTE ON PANEL ACTION:
AFFIRMATIVE: 12

(Log #1351)

3- 87 - (690-3): Accept in Principle
SUBMITTER: David P. Brown, Baltimore Gas and Electric Co/EEI
COMMENT ON PROPOSAL NO: 3-150
RECOMMENDATION: This proposal should be accepted in principle.
SUBSTANTIATION: The EEI Electric Light and Power Group is concerned about assuring the safety of utility workers when working on systems supplied by both utility and distributed generation sources. Also, output characteristics of distributed generation equipment must be controlled so as not to cause objectionable effects on the electric supply to other users.
The requirements of Article 705 should apply to installations of interconnected solar power production systems installed under the provisions of Article 690 and intended to be operated in parallel with the supply to the premises wiring. Specifically, the requirements of Section 705-12 Point of Connection, Section 705-14 Output Characteristics, Section 705-22 Disconnect Device, and Section 705-40 Loss of Primary Source need to be incorporated into Article 690, Part G.
Section 705-12 Point of Connection is necessary to ensure that interconnected power production systems are connected to the premises wiring system at the service rather than on a feeder or a branch circuit as permitted by 690-64(b).
Section 705-14 Output Characteristics is necessary to ensure that interconnected power production systems do not adversely affect the supply system by outputting power with improper wave shape, voltage, or frequency. This requirement is necessary to limit harmonic distortion on supply voltage for other customers served from the electric utility supply system.
Section 705-22 Disconnect Device is necessary to provide a method of disconnecting the interconnected power production system from the electric supply system when the solar photovoltaic system malfunctions or requires maintenance.
Section 705-40 Loss of Primary Source and Section 690-61 should be identical. Upon loss of primary source, all electric power production sources shall be automatically disconnected from all ungrounded conductors of the primary source and shall not be reconnected until the primary source is restored.
Considering the application of Article 705 rules within Article 690, provides for the safety of the premises wiring system, the utility supply system, and anyone working on those systems when photovoltaic systems are operated in parallel with the utility supply.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: See panel action and statement on Comment 3-88.

VOTE ON PANEL ACTION:
AFFIRMATIVE: 12

(Log #1866)

3- 88 - (690-3): Accept in Principle
SUBMITTER: Timothy M. Croushore, Allegheny Power
COMMENT ON PROPOSAL NO: 3-150
RECOMMENDATION: Code Making Panel 3 should accept Proposal 3-150.
SUBSTANTIATION: The panel should have accepted this proposal or included the language in Article 690 as indicated by Mr. Horman. The Article should govern the general requirements of Interconnected Electric Power Production Sources including solar and photovoltaic sources. I disagree with the panel statement. This was not a 6 cycle issue as indicated in the panel statement. These systems have not been installed without Article 705 for the last 15 years. And the requirements of Article 705 are for both rotary and inverter type technology.
As a former member of Code Making Panel 3, I must report that this was not an issue until the 1999 NEC. In fact, the Article 705 requirements were removed with very little technical substantiation for the change. Please review the old ROP page 1018, Proposal 3-213 and the old ROC page 695, Comment 3-173.
As indicated by Mr. Horman the requirements in Sections 705-12 - Point of Connection, 705-14 - Output Characteristics, 705-22 - Disconnect Device, and 705-40 - Loss of Primary Source are absolutely essential for safety for all interconnected parallel power production equipment regardless of the technology. These requirements apply to both rotating and inverter technology.
Based on this information, the NEC language should go back to the language of 1996 text or this proposal should be accepted.
PANEL ACTION: Accept in Principle.
Change the proposed text in Proposal 3-150 to read as follows:
690.3 Other Articles. Wherever the requirements of other articles of this Code and Article 690 differ, the requirements of Article 690 shall apply and, if the system is operated in parallel with a primary source(s) of electricity, the requirements in 705-14, 705-16, 705-32, and 705-43 shall apply.
PANEL STATEMENT: The text was revised to more adequately cover the interconnection between the photovoltaic power system and a utility supply, an on-site electric power source, or some other type of electric power source. By including compliance with the applicable requirements in Article 705, the PV system can remain under the installation requirements of Article 690 and, at the same time, comply with the interconnection requirements necessary for safety where dealing with a parallel power installation.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 12
VOTE ON PANEL ACTION:
AFFIRMATIVE: 12
COMMENT ON AFFIRMATIVE:
HORMAN: The EEI Utility Task Force commends the panel on their efforts to address these important performance and safety issues. The utilities still feel 705-12 should apply to solar photovoltaic systems when operated in parallel with a primary source of electricity. Having the interconnection for parallel operation with a utility delivery system located at the premises service disconnecting means would make these systems safer for utility workers.

(Log #2161)

3- 89 - (690-4(b)): Reject
SUBMITTER: Patrick B. Kiernan, Eco Electric, Inc.
COMMENT ON PROPOSAL NO: 3-151
RECOMMENDATION: This proposal should be accepted, to retain consistency with the rest of the NEC.
SUBSTANTIATION: Section 300-3(c)(1) allows conductors of different systems in the same enclosure, cable, or raceway. Solar photovoltacs are the only noted exception. What technical substantiation supports this exception?
PANEL ACTION: Reject.
PANEL STATEMENT: The primary reason for not allowing PV source and PV output circuits to be installed in the same raceway, cable tray, cable outlet box, junction box, or similar fitting with feeders or branch circuits of other systems is to keep these systems totally separate to ensure the two systems are not inadvertently interconnected. The PV system should not be installed with telecommunications circuits or radio frequency circuits as stated in the substantiation for the proposal since this would be in violation of Sections 800-52(a)(1)(c) and 820-52(a)(1)(b) unless a barrier or some other separator was used.
The use of a disconnecting means does not have anything to do with the mixing and possible interconnection of PV power system conductors and other power source wiring systems. The PV power systems are unique enough to require separation from other power source conductors. Section 90-3 permits Article 690 to modify the requirements in Chapters 1 through 4.

VOTE ON PANEL ACTION:
AFFIRMATIVE: 12

(Log #980)

3- 93 - (690-6(d)): Reject
SUBMITTER: John C. Wiles, Jr., Southwest Tech. Development Inst.
COMMENT ON PROPOSAL NO: 3-165 and 3-168
RECOMMENDATION: This section should be removed from the 2002 Code.
SUBSTANTIATION: Some authorities having jurisdiction are interpreting this section as mandatory or are requiring that the permissive requirements be met. PV designers and installers are unable to find any listed equipment that is specifically identified for this application and they are using receptacle-type ground-fault circuit interrupters (GFCIs), circuit breaker GFCIs, and Equipment Protection Ground Fault Circuit Breakers in an attempt to meet the authorities having jurisdiction requirements. The use of this equipment creates a possibly hazardous and unsafe situation.

Research and testing by Sandia National Laboratories and The Southwest Technology Development Institute at New Mexico State University have established conclusively that these devices should not be used for this application. When improperly used as required by this application, these devices can and do create hazardous conditions as well as destroy themselves. I have provided an IEE paper that provides full details.

Section 690.6(D) should be removed from the 2002 NEC and not reentered into the Code until a class of devices can be developed that will safely meet this requirement. To keep the section in the code, will continue to cause confusion among the authorities having jurisdiction and PV designers and installers and endanger the public.

Note: Supporting material available for review upon request at NFPA headquarters.
PANEL ACTION: Reject.
PANEL STATEMENT: There is no technical justification given to delete this section and the reasons given revolve around the misuse of the terms ground-fault protection of equipment versus ground-fault circuit-interrupter protection. Ground-fault protection of equipment is designed to protect equipment from damaging line to ground faults. The IEEE paper submitted as technical substantiation appeared to mix both categories of GFP and GFCI devices and was not conclusive in its differentiation between the two very different systems.

There are also several different methods to provide ground-fault protection of equipment, with circuit breakers being just one of the methods. Differential transformers connected to relays and other similar equipment could provide protection for the system. The text is permissive, not mandatory, so the installer would not be required to supply GFP of equipment.

3- 94 - (690-9(c)): Accept
SUBMITTER: John C. Wiles, Jr., Southwest Tech. Development Inst.
COMMENT ON PROPOSAL NO: 3-177
RECOMMENDATION: In the first sentence of the second paragraph, the words "fuse-type" should be removed.
SUBSTANTIATION: Supplementary circuit breakers are also available in these incremental 1-amp sizes from 1 amp to 15 amps and are fully suitable for the use.
PANEL ACTION: Accept.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 12
VOTE ON PANEL ACTION:
AFFIRMATIVE: 12

(Log #2154)

3- 95 - (690-14(c)): Reject
SUBMITTER: Patrick B. Kiernan, Eco Electric, Inc.
COMMENT ON PROPOSAL NO: 3-182
RECOMMENDATION: Accept proposal 3-182 as submitted.
SUBSTANTIATION: The text proposed by panel action could require a PV disconnect where the conductors enter the structure and where the other system disconnects are grouped.
PANEL ACTION: Reject.
PANEL STATEMENT: The text in Section 690-14 in the 1999 NEC required compliance with Article 230 Part F. The panel action in Proposal 3-182 provided the required text to ensure that the disconnecting means for PV systems would be located as required for a standard service disconnecting means, except as modified by Article 690. The required disconnecting means provides a location where the building or structure could be disconnected from power during an emergency or other similar situation.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 12
VOTE ON PANEL ACTION:
AFFIRMATIVE: 12

(Log #2160)

3- 96 - (690-14(c)): Reject
SUBMITTER: Patrick B. Kiernan, Eco Electric, Inc.
COMMENT ON PROPOSAL NO: 3-182
RECOMMENDATION: Accept the original proposal as written.
SUBSTANTIATION: The adaptation of Part F of Article 230 is inappropriate. The photovoltaic disconnecting means should not be treated as service equipment. (See substantiation for Proposal 3-181.)
PANEL ACTION: Reject.
PANEL STATEMENT: The submitter did not provide any technical substantiation that the photovoltaic system should not be required to comply with the added requirements similar to services, such as grouping, marking, location of the disconnect, maximum number of disconnects permitted in one location, and suitability of use. The substantiation in Proposal 3-181 did not provide technical substantiation either.

(Log #2023)

3- 98 - (690-41): Accept in Principle
Note: The Technical Correlating Committee understands that in the Panel Action the revised text of 695-41 begins with "For photovoltaic" and ends with "identified for the use." In addition, the reference to 690-41 Exception in Section 690-71(A) will appear as 690-41.
SUBMITTER: Frederic P. Hartwell, Hartwell Electrical Services, Inc.
COMMENT ON PROPOSAL NO: 3-187
RECOMMENDATION: Restore the listing requirement, as follows:
"... other listed methods that accomplish equivalent system protection ..."
SUBSTANTIATION: The statement in the proposal substantiation, unchallenged by the panel, that all equipment in the Code is required to be listed is news to this member of the NEC Committee. Every cycle we have robust discussions as to when a listing requirement is excessive in Code-Making Panel 9. Equipment used for this procedure, however, should be listed because the authority having jurisdiction won't be able to determine suitability in the field. The listing requirement proposed by this comment is comparable to 250.164(B)(3).
PANEL ACTION: Accept in Principle.
Add the phrase "and that utilize equipment listed and identified for the use" at the end of the recommended text in the proposal to read as follows:
For a photovoltaic power source, one conductor of a two-wire system with a system voltage over 50 volts and the reference (center tap) conductor of a bipolar system shall be solidly grounded or shall use other methods that accomplish equivalent system protection in accordance with 250-2(a) and that utilize equipment listed and identified for the use. The panel notes that there is a reference in 690-71 to an exception in 690-41. This exception has been integrated into the text of 690-41 and the reference to the exception should be deleted.
PANEL STATEMENT: Adding the phrase "and that utilize equipment listed and identified for the use" meets the intent of the comment submitter while making it clear that equivalent system protection must be listed and identified for that use.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 12
VOTE ON PANEL ACTION:
AFFIRMATIVE: 12
COMMENT ON AFFIRMATIVE:
KREINER: The recommended text in the Panel Action is complete at the end of the phrase "... that utilize equipment listed and identified for the use."
The last two sentences in the Panel Action should be a separate action to remove the reference to "Section 690-41, Exception" in Section 690-71(a) and change the reference in Section 690-71(a) to "690-41."

(Log #2158)

3- 99 - (690-43): Accept in Principle in Part
SUBMITTER: Patrick B. Kiernan, Eco Electric, Inc.
COMMENT ON PROPOSAL NO: 3-188
RECOMMENDATION: Clarification of my Proposal 3-188.
SUBSTANTIATION: Article 250-136(a) implies that metal framed photovoltaic modules secured to and in electrical contact with a grounded metal support rack, shall be considered effectively grounded. There is no mention of separate bonding jumpers between each piece of equipment.
PANEL ACTION: Accept in Principle in Part.
Change the existing text in the 1999 NEC by adding the specific references in Article 250 to better comply with the NEC Style Manual to read as follows:
690-43. Equipment Grounding
Exposed noncurrent-carrying metal parts of module frames, equipment, and conductor enclosures shall be grounded in accordance with Section 250-134 or 250-136(a) regardless of voltage.
Reject the remainder of the recommended text in the proposal.
PANEL STATEMENT: This comment does not comply with Section 4-4.5(c) of the NFPA Regulations Governing Committee Projects requiring comments to provide a recommendation. The panel changed the existing text in the 1999 NEC by adding the specific references in Article 250 to better comply with the NEC Style Manual and by making this change satisfied the submitter's concern. By adding the reference to 250-136(a), the last sentence in the recommended text in the proposal becomes redundant and not necessary.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 12
VOTE ON PANEL ACTION:
AFFIRMATIVE: 12

(Log #983)

3- 100 - (690-45): Accept
SUBMITTER: John C. Wiles, Jr., Southwest Tech. Development Inst.
COMMENT ON PROPOSAL NO: 3-189
RECOMMENDATION: Suggest the section be reworded as originally submitted.
SUBSTANTIATION: Part 1 - Delete the first sentence of Section 690-45. The following sentence should be deleted:
"The equipment grounding conductor shall not be smaller than the required size of the circuit conducts in systems where the available photovoltaic power source short-circuit current is less than twice the current rating of the overcurrent device."
1. Overcurrent devices (and conductor ampacity) in circuits carrying currents from PV modules are generally sized at least at 156 percent (1.25 x 1.25) of the circuit short-circuit available from the PV arrays. (690-8(a)(1) and 690-8(b). This guarantees that the overcurrent device will not open due to currents from the PV source that normally flow through that overcurrent device. The overcurrent device in a PV source circuit is required to be rated at least at 1.56 times the short-circuit current from that PV source (690-8). In other words, the short-circuit current is less than or equal to 0.64 times (1/1.56) the overcurrent device rating. This short-circuit current from the PV source will always be less than twice the rating of the overcurrent device for source circuit.
2. Overcurrent devices must be located in a circuit at the source of possible overcurrents. (240-3, 240-21)
a. From 1, above, the PV module or modules on a given PV source circuit cannot be a source of overcurrents for any overcurrent device on that same circuit and therefore overcurrent devices for these circuits are not located at the module end of the circuits.
b. Parrallel-connected modules, backfeed from batteries and backfeed from utility-interactive inverters are the sources of potential overcurrents that will open overcurrent devices under PV source fault conditions.
c. Items 2a and 2b dictate that the overcurrent device for PV source circuits be located at the end of the circuit (away from the PV modules) where these potential overcurrents originate.
3. Potential overcurrents from the sources are usually far in excess of the rating of the PV overcurrent device in question which is rated at least 1.56 Isc for the circuit.
a. Potential overcurrents from batteries are in the thousands of amps range, far higher that any short-circuit current possible from the PV module or PV array, but may be limited by any additional overcurrent device(s) between the battery and PV circuits.
b. Potential backfeed from utility interactive inverters will be limited to any overcurrent devices in either the ac or dc line to the inverter but in general will be significantly higher than Isc of the PV circuit.
c. Potential backfeed currents from parallel-connected modules will increase at the rate of 1.25 Isc for each separate parallel connected circuit and even two parallel strings will provide 2.5 times the rated short-circuit current (Isc).
4. Because of the above considerations, the first sentence in Section 690-45 does not make sense and will be true in very, very few cases, if ever. The revised proposal will cover this case since it

requires that the equipment-grounding conductor always be as large as the circuit conductors except under special circumstances.

Part 2 Make the equipment-grounding conductors as large as the circuit conductors in PV source and output conductors.

1. In Part 1, we have established that overcurrent devices in PV circuits are located, not at the PV modules, but at the other end of the circuit, some distance away.

2. Now consider a ground-fault on the PV side of the overcurrent device such as the positive module conductor of the PV module coming into contact with the grounded PV array frame. This is Ground Fault A in Figure 1 and the fault currents are shown as straight arrows. The overcurrent device in the circuit will open if there are sufficient sources of backfeed current (shown as the wide based arrow). However, no matter whether the overcurrent device opens or not, the PV source will continue to feed energy into the fault as long as the sun shines. From Figure 1, we can see that the PV fault currents leave the positive terminal of the module, travel into the frame through the fault path, flow down the equipment grounding conductor to the negative conductor-to-ground bond, through the bond, and then back to the negative terminal of the module.

3. This fault current may be a continuous current at 1.25 Isc. To avoid hazards associated with overheating of the equipment-grounding conductor, it should be able to handle this current which requires that it be sized the same as the circuit conductors. This is why Underwriters Laboratories requires that recently-listed PV Source-Circuit Combiner Boxes have equipment grounding terminal provisions that can accept conductors as large as the largest circuit conductor.

4. The same argument applies to PV output circuits that are the combined output of PV source circuits. In this case, ground faults in the circuit between the Source Circuit Combiner Box (Ground Fault B) and the last overcurrent device (nearest the load) will cause circulating continuous currents (shown as wavy arrows) in the equipment-grounding conductor.

Part 3 The requirements dictated by Article 690-5 for ground-fault protection for PV systems mounted on the roofs of dwellings modify the basic requirement proposed above.

1. If the PV system meets the 690-5 requirements, then any ground-fault in the PV circuits will result in an interruption of the fault currents and the equipment-grounding conductor will not have to carry continuous fault currents. In these cases, the equipment-grounding conductors should be sized according to Section 250-122.

NOTE: Supporting Material is available for review at NFPA Headquarters.

(Log #2155)

3- 101 - (690-47): Reject
SUBMITTER: Patrick B. Kiernan, Eco Electric, Inc.
COMMENT ON PROPOSAL NO: 3-190
RECOMMENDATION: I am requesting clarification.
SUBSTANTIATION: Is a grid tied photovoltaic system with multiple DC source circuits, no batteries, and an inverter considered DC, AC or both?

Is a stand alone photovoltaic system with batteries, inverter and AC and DC loads considered an AC system, DC system, or both?
PANEL ACTION: Reject.
PANEL STATEMENT: The comment was rejected since it did not comply with Section 4-4.5 of the NFPA Regulations Governing Committee Projects requiring the comment to provide a recommendation of action. The comment on proposals is not the proper format for asking for clarification on a particular issue within the Code. There are formal and informal interpretation request forms that may be filled out and submitted either to the panel or to NFPA Staff to provide answers to questions, such as the ones sent in with this comment.

(Log #2156)

3- 102 - (690-56): Reject
SUBMITTER: Patrick B. Kiernan, Eco Electric, Inc.
COMMENT ON PROPOSAL NO: 3-194
RECOMMENDATION: Reject Proposal 3-194.
SUBSTANTIATION: This sounds like a reasonable idea to improve safety. But several issues need to be resolved before it is committed to code. For example, how large is the required plaque? Can the Authority Having Jurisdiction require it to be on your front door?
PANEL ACTION: Reject.
PANEL STATEMENT: The recommended text in the panel action for Proposal 3-194 places the responsibility on the authority having jurisdiction (AHJ) for determining the location of the plaque or directory. The purpose for having the AHJ determine the location of the plaque or directory is to allow it to placed at the location where emergency crews will be accessing the building, thus warning them that a separate power source is in the building or structure and providing information to them on disconnect locations and other pertinent information on the system.

(Log #984)

3- 103 - (690-64(b)(5)): Reject
SUBMITTER: John C. Wiles, Jr., Southwest Tech. Development Inst.
COMMENT ON PROPOSAL NO: 3-195
RECOMMENDATION: This section should be deleted as originally submitted.
SUBSTANTIATION: Background. Some sort of disconnect and overcurrent device must be provided on the dedicated output circuit of a utility-interactive inverter where that circuit connects to the utility line to meet the requirements of Article 690 and other NEC requirements. While a fused disconnect may be used, it is far more common to use a circuit breaker to meet these requirements.

This section in Article 690 was placed in the code in the early days of PV systems to ensure proper operation of circuit breakers under all conditions of operation and fault interruption. The internal construction of some circuit breaker trip mechanisms and arc-suppression devices is designed so that the circuit breaker can meet listing standards only when interrupting fault currents flowing in a certain direction. Such circuit breakers have terminals marked "load" and "line" or may be marked "Not suitable for backfeeding" [UL Standard 489].

In the ac output circuit of a utility-interactive PV inverter, power flow through the final dedicated circuit-breaker contained in a service entrance panel is normally backward through the breaker at maximum current levels of 80 percent of the circuit breaker rating or less. These utility-interactive inverters are typically power-limited devices and cannot supply high surge currents such as those that might be available from a voltage-sourced, rotating ac generator. Under normal operation, opening and closing the breaker will subject it to currents that are no more than 80 percent of the breaker rating.

When a fault (line-to-ground or line-to-line) of sufficiently low impedance occurs in the ac output circuit of the utility-interactive inverter, two things occur. The inverter senses a loss of nominal utility voltage and starts to shut down due to its internal safety circuits. Current flows through the circuit breaker in the forward direction from the utility toward the fault, and those faults cause the breaker to trip in the normal manner. There can be no back feeding of fault currents through the circuit breaker.

In the case where the circuit breaker is a separate unit and not part of a service entrance panel, a fault between the breaker and the service entrance will only cause the inverter to shut down and the breaker will not even sense currents in excess of its rating.

To summarize: A circuit breaker, where used, as an overcurrent device in the output of a utility-interactive inverter operates in a normal manner and cannot be subjected to backfeed fault currents. This was not true in the early days of PV systems when this code section was added because utility-interactive inverters were neither listed nor identified for the use and could operate in island situations backfeeding the service entrance for long periods of time like voltage-sourced rotating generators.

This section is no longer needed in the code and causes confusion among PV designers and installers as well as authorities having jurisdiction.

PANEL ACTION: Reject.
PANEL STATEMENT: One of the reasons for requiring the identification of backfed breakers is to warn the operator/maintainer that the circuit breaker may be receiving energy as a result of being backfed from a source of power. It is a safety requirement for the maintainer more than it is a function of how and whether the device will operate in a fault situation. Section 110-22 requires identification of disconnecting means and Section 384-16(g) requires backfed circuit breakers to be secured in place.

(Log #986)

3- 107 - (690-71(g)): Accept in Principle
SUBMITTER: John C. Wiles, Jr., Southwest Tech. Development Inst.
COMMENT ON PROPOSAL NO: 3-199
RECOMMENDATION: Suggest rewording the first sentence by changing the word "grounds" to "grounded circuit conductor or conductors".
SUBSTANTIATION: The word "grounds" is confusing and may be interpreted as meaning all grounded conductors including the equipment-grounding conductors. There is no intent to ungrounded equipment grounding conductors, which is neither a safe nor easy operation in a grounded battery bank where metal racks and cases rest on a concrete floor.
PANEL ACTION: Accept in Principle.
Change the word "grounds" in the first sentence and the word "ground" in the second sentence to "grounded circuit conductor(s)" to read as follows:
(f) Battery Maintenance Disconnecting Means. Battery installations, where there are more than twenty four (24), 2-volt cells connected in series (48 volts nominal), shall have a disconnecting means, accessible only to qualified persons, that disconnects the grounded circuit conductor(s) in the battery electrical system for maintenance. This disconnecting means shall not disconnect the grounded circuit conductor(s) for the remainder of the photovoltaic electrical system. A non-load-break rated switch shall be permitted to be used as the disconnecting means.
PANEL STATEMENT: There were two locations within that section that needed clarification for the word "ground."

(Log #988)

3- 109 - (690-85): Reject
SUBMITTER: John C. Wiles, Jr., Southwest Tech. Development Inst.
COMMENT ON PROPOSAL NO: 3-205
RECOMMENDATION: The proposed definitions Section 690.85 now creates two Definitions Sections in Article 690, 690.85 and 690.2.
Suggest that the two paragraphs, Battery Circuits and Photovoltaic Source Circuits be moved to Section 690.7 as 690.7(F), and 690.7(G).
SUBSTANTIATION: This removes the redundant Definitions Section. It also puts the voltage definitions in Section 690.7 where voltage is addressed.
Furthermore, these voltage definitions, apply to all PV systems having PV modules and/or batteries and may have implications in other than Part 1 of Article 690. It does not seem proper to restrict the definitions to Part 1 only.

PANEL ACTION: Reject.
PANEL STATEMENT: Since these definitions apply specifically to those installations that are over 600 volts, it is perfectly acceptable and, in fact, desirable to have them at the location where they will be used.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 12
VOTE ON PANEL ACTION:
AFFIRMATIVE: 12

(Log #1481)

3- 110 - (690 Part I):
Note: The Technical Correlating Committee directs that this Comment be reported as "Reject" since in the 2002 NEC, Part Numbers will be indicated by Roman Numerals.
SUBMITTER: Ivan DeWitt, Holland, MI
COMMENT ON PROPOSAL NO: 3-204
RECOMMENDATION: Change Part "I" to Part "J". (No other changes in heading)
SUBSTANTIATION: The letters I and O have been omitted as identification of the headings in the format of the articles of the NEC to eliminate any possible confusion with the numbers one and zero. Article 690, Part I is not consistent with this format and the style manual of the NEC.
Reference: Articles 250, 410, 424, 430 and 620 (1999 Edition)
Proposal 10-76 (240 Part I) May 2001 ROP.
PANEL ACTION: Accept.

(Log #36)

3- 111 - (691 (New)): Accept
SUBMITTER: Technical Correlating Committee National Electrical Code
COMMENT ON PROPOSAL NO: 3-206
RECOMMENDATION: The Technical Correlating Committee advises that Article Scope statements are the responsibility of the Technical Correlating Committee. The Technical Correlating Committee directs that the second sentence of the proposed Scope be deleted and considered for inclusion in a definition.
The Technical Correlating Committee directs that a new title "Fuel Cell Systems" be used and the Article be renumbered as Article 692.
The Technical Correlating Committee further directs the panel to remove the term "nationally recognized testing laboratory" from 691-6 since this term is specific to OSHA approval and the definition of listing in Article 100 is sufficient to describe the requirements for a laboratory. The Technical Correlating Committee directs that the Panel review the proposed text to eliminate the references to complete Articles in 691-3, 691-10(b), 691-14, and 691-80, in accordance with the NEC Style Manual. This action will be considered by the Panel as a Public Comment.
SUBSTANTIATION: This is a direction from the National Electrical Code Technical Correlating Committee in accordance with 3-4.2 and 3-4.3 of the Regulations Governing Committee Projects.
PANEL ACTION: Accept.
In 692-6 delete the phrase "by a nationally recognized testing laboratory".
Amend 692-3 to read:
692-3 Other Articles. Wherever the requirements of other articles of this Code and Article 692 differ, the requirements of Article 692 shall apply and, if the system is operated in parallel with a primary source(s) of electricity, the requirements in 705-14, 705-16, 705-32, and 705-43 shall apply.
In 692-10(b) change reference to "Article 240" to "240-3".
Revise the first sentence of Section 692-14 to read:
The provisions of Sections 225-31, and 225-33 through 225-40 shall apply to the fuel cell source disconnecting means.
In 692-80 delete the words "Article 490 and".

VOTE ON PANEL ACTION:
AFFIRMATIVE: 12

(Log #2346)

3- 115 - (691-6(b)): Accept in Part
SUBMITTER: Kenneth Krastins, Plug Power, Inc.
COMMENT ON PROPOSAL NO: 3-206
RECOMMENDATION: Revise the second and third sentence of 691-6(b) to read:
691-6. Listing Requirement. The fuel cell system shall be evaluated and listed (as defined in Article 100).
SUBSTANTIATION: The existing proposed wording is too vague. By referencing Article 100, the definition of listed is made more clear. Also, "nationally recognized testing laboratory" typically refers to government agencies like Sandia Labs rather than independent, third-party listing organizations, such as UL.
PANEL ACTION: Accept in Part.
The panel accepts the deletion of "nationally recognized testing laboratory", and rejects the addition of "(as defined in Article

100)". The wording shall read:
692.6 Listing Requirement. The fuel cell system shall be evaluated and listed for its intended application prior to installation.
PANEL STATEMENT: This section was revised in Comment 3-111 based on direction from the Technical Correlating Committee. The reference to Article 100 was deleted to eliminate a redundant reference.

(Log #310)

15- 71 - (695-4(b)(1)): Accept
SUBMITTER: R. Schneider, Joslyn Clark Controls, Inc.
COMMENT ON PROPOSAL NO: 15-88
RECOMMENDATION: CMP 15 action should be changed from "Accept" to "Reject."
SUBSTANTIATION: a) This is extracted material which can only be revised by the NFPA 20 committee.
b) No such listed product exists. Instantaneous trip circuit breakers have never been used as a service because they do not comply with Article 230. Feeders under 695-6(b) need not be encased in concrete thus, in absence of overload protection, can become incendiary source.
c) Adj. trips makes compliance with 240-12 subject to tampering, difficult to design and inspect.
PANEL ACTION: Accept.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 18
VOTE ON PANEL ACTION:
AFFIRMATIVE: 18

(Log #854)

15- 72 - (695-4(b)(1)): Accept
SUBMITTER: Larry F. Miller, National Electrical Manufacturers Association (NEMA)
COMMENT ON PROPOSAL NO: 15-88
RECOMMENDATION: The panel should reject this proposal.
SUBSTANTIATION: 1. Instantaneous trip circuit breakers are component recognized, which means that they are incomplete in one or more features and that the evaluators must examine each device for completeness in its equipment and application. The major points on which instantaneous trip circuit breakers are incomplete is that (a) they have no overload protection and (b) they have no marked interrupting rating. There may be other points in the recognition report covering the device on which they would need to be evaluated.
2. Since the instantaneous trip circuit breaker does not have an interrupting rating it, cannot be evaluated for compliance with 110-9 and 110-10 without additional testing.
3. An instantaneous trip circuit breaker is permitted under 430-52(c)(3) and 430-109 only when it is a part of a listed combination motor controller. Product standard requirements for listing of the combustion motor controller cover coordinated overload protection, short circuit testing and other requirements for appropriate use of the instantaneous trip circuit breaker. This proposal does not provide for this additional evaluation except by the authority having jurisdiction.
4. Specific requirements for fire pump controllers devices appear in NFPA 20.
PANEL ACTION: Accept.

(Log #1779)

15- 74 - (695-4(b)(1)): Accept
SUBMITTER: Jim Pauley, Square D Company
COMMENT ON PROPOSAL NO: 15-88
RECOMMENDATION: The panel should reconsider and reject the proposal.
SUBSTANTIATION: Although the proposal has a good intent, the use of an instantaneous trip circuit breaker in this application would be contrary to the listing of the breaker. Instantaneous trip breakers are permitted by Article 430 only when part of a combination motor controller. The reason for this restriction in Article 430 is that these breakers are component recognized (meaning they have limitations of use that must be considered in their final application in equipment) and they have no marked interrupting rating (because this rating is established based on the application in the equipment).
PANEL ACTION: Accept.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 18
VOTE ON PANEL ACTION:
AFFIRMATIVE: 18

(Log #2144)

15- 75 - (695-4(b)(1)): Accept
SUBMITTER: James S. Nasby, Master Control Systems, Inc.
COMMENT ON PROPOSAL NO: 15-88
RECOMMENDATION: Reject the proposal.
SUBSTANTIATION: This proposal suggests dramatic changes (reduction) to long standing coordination ratings of a device in the so-called Critical Starting Path of an Electric Motor Driven Fire Pump.
It would reduce the extant Locked Rotor (typically 600 percent) thermal and hold (no trip) current ratings down to 125 percent or less. No minimums are given.
1) The proposal addresses an Overcurrent Device when used up stream of a Fire Pump Controller or Fire Pump Power Transfer Switch or a Combination Fire Pump Controller and Power Transfer Switch. Presently, when such a device is used, it must be "sized to carry indefinitely the sum of the locked-rotor current of the fire pump motor(s) and" other connected loads. This leaves

the overcurrent protection of the wiring in the downstream Fire Pump Controller. This protection is set to hold (not trip) 300 percent, as a minimum, of the motor FLA. The proposed device reduces the 600 percent requirement to as little as 125 percent of the motor FLA. This is a 480 percent reduction of the thermal and trip capability of the device in line with the power source. This would not be coordinated with the Fire Pump Controller mandated overcurrent protection (300 percent). It would move overcurrent responsibility outside of the Listed Fire Pump Controller and place it into undefined and unknown hands.

2) The subject paragraph is extract material. See Appendix A, 695-4 (NFPA-20-1999 paragraph 6-2.4.3 and 6-3.2.2).

3) When such an upstream device is allowed and used, it is almost always the Service Entrance device. I believe that most jurisdictions (electrical inspectors or utility installers) require the Service Entrance device to be a UL Listed Service Entrance device or a Listed Service Entrance rated device.

PANEL ACTION: Accept.

(Log #2142)

15- 76 - (695-6): Reject
SUBMITTER: James S. Nasby, Master Control Systems, Inc.
COMMENT ON PROPOSAL NO: 15-93
RECOMMENDATION: Change the proposal to add a new sentence to 695-6(b) to read:

These fire pump supply conductors include wiring from the on-site stand-by generator to the alternate source side of a fire pump controller or fire pump power switch or a combination fire pump controller and power transfer switch.

SUBSTANTIATION: It was the impression of the submitter, me, that the 2 in. concrete (or one hour fire resistance rating) did <u>not</u> apply to the feeders from the stand-by (alternate, emergency) generator. Moreover, I believe that it isn't common practice at this time. Hence, the Code-Making Panel-15 Panel Statement in the Proposal 15-93 rejection states that 695-6(b) <u>is</u>, indeed, "intended to apply to feeder conductors from a generator".

If so, I don't think it's common knowledge and has not been common practice in the past. I don't know if this requirement (fire protection of the alternate side power wiring) has ever been subjected to comments or votes. It may be new business, which is why I have suggestrd the rewording of my proposals 15-93 and 15-96.

In any case, the above revised proposal attempts to add text to clearly state the Panel's stated intention.

The submitter still receives numerous questions from the field on the question of protection of the alternate source side wiring.

PANEL ACTION: Reject.
PANEL STATEMENT: The proposed new sentence is not necessary and does not provide any clarification. The existing text is clear in its intent.

(Log #2143)

15- 77 - (695-6 Exception No. 2 (New)): Reject
SUBMITTER: James S. Nasby, Master Control Systems, Inc.
COMMENT ON PROPOSAL NO: 15-96
RECOMMENDATION: Accept in Principle the proposal by changing the proposed two proposed exceptions to one newly worded exception.

Add a second exception to 695-6(b) and number the existing one as Exception No. 2:

Exception No 2: Where the installation does not fall under the requirements of Section 700-9d(1), the conductors from a generator to the alternate source terminals of a fire pump controller or fire pump power transfer switch or a combination fire pump controller and power transfer switch need not meet the above one hour fire resistance when these conductors meet all of the following requirements: 1) they are protected by a branch circuit breaker complying with Section 240-3 (and 310-15); 2) they supply loads that are directly associated with the fire pump system; 3) they are protected to resist potential damage by fire, structural failure or operational accident; and 4) they are <u>not</u> routed through a building(s).

SUBSTANTIATION: The purpose is to clarify the protection required for the conductors from a generator to the alternate source terminals for a fire pump.

The submitter realized that this proposal and comment need to coordinate with the submitter's Proposal 15-93 and with Accepted Proposal 15-97 and with Sections 695-3(b)(1) and Section 700-9(d)(1).

Definitive language is needed on the 2 in. concrete requirements for engineering, installation and inspection personnel.

PANEL ACTION: Reject.
PANEL STATEMENT: The conductors need the necessary protection.

VOTE ON PANEL ACTION:
AFFIRMATIVE: 18

(Log #2286)

15- 78 - (695-6(b)): Accept in Principle in Part
SUBMITTER: James M. Daly, BICC General
COMMENT ON PROPOSAL NO: 15-94
RECOMMENDATION: The Proposal should continue to be Accepted in Principle in Part.

The Panel Action should be revised as follows:

Fire pump supply conductors on the load side of the final disconnecting means and overcurrent device(s) permitted by Section 695-4(b) shall be kept entirely independent of all other wiring. They shall only supply loads that are directly associated with the fire pump system, and they shall be protected to resist potential damage by fire, structural failure, or operational accident. They shall be permitted to be routed through a building(s) using one of the following ~~conditions~~ <u>methods</u>:

(1) Be encased in a minimum 50 mm (2 in.) of concrete

(2) Be within an enclosed construction dedicated to the fire pump circuit(s) and having a minimum of a 1-hour fire resistive rating

(3) Be a listed cable or listed electrical circuit protection system with a minimum of 1-hour fire rating. <u>Flammable products of combustion shall not be permitted to enter enclosures containing arcing or sparking devices.</u>

Exception: The supply conductors located in the electrical equipment room where they originate and in the fire pump room shall not be required to have the minimum 1-hour fire separation or fire resistance rating, unless otherwise required by Section 700-9(d) of this Code.

SUBSTANTIATION: Changing "conditions" to "methods" is more consistent with the example in Section 2.1.5.3 of the NEC Style Manual and is more descriptive of the list following.

Insulated conductors in raceways and multiconductor cables may qualify as a fire resistive wiring method; however, some of the new polymeric insulations and jackets produce flammable gases during decomposition under fire conditions. The insulation, and jacket where used, is actually designed to burn with the resulting residue providing electrical insulation.

UL2196, Standards for Tests for Fire Resistive Labels, only measures the fire resistance properties and does not measure combustible smoke/gases generated during decomposition.

These flammable gases can travel through the cable and, even more readily, through a conduit and enter enclosures that contain arcing or sparking devices resulting in an explosion. Provisions must be made to prevent the entrance of these combustible gases into the enclosures.

The additional text is only required in method (3) since methods (1) and (2) prevent the conductor insulation from being exposed for at least 1 hour to temperatures that could cause combustion of the insulation. Concrete encasement of conduit containing insulated conductors or cable, gypsum board enclosures around conduit containing insulated conductors or cable, and any of the intumescent wraps used on cable or conduit, all function to keep the temperature low enough at the conductor insulation so it will not burn. Type MI cable when exposed directly to a fire will continue to operate, will not burn, decompose, or generate any combustible gases or smoke.

The proposed new wording also incorporates revisions made by the Panel in Proposals 15-91 and 15-94.

PANEL ACTION: Accept in Principle in Part.
The panel accepts the revision of "conditions" to "methods."
The panel rejects the new sentence in item (3).
In addition, in item (3) delete "listed cable or".

PANEL STATEMENT: With regard to the rejected sentence, the method by which flammable products of combustion are prevented from entering enclosures has not been described. More information about the quantities of flammable gases and the conductor's insulation that create these gases is needed.

The panel has deleted "listed cable or" because a standard does not yet exist for listed cable. The panel considered Dr. Hirschler's negative comment on Proposal 15-94.

VOTE ON PANEL ACTION:

AFFIRMATIVE: 18

(Log #2146)

15- 79 - (695-6(b)3): Accept in Part

SUBMITTER: James Conrad, Rockbestos-Surprenant Cable Corp.

COMMENT ON PROPOSAL NO: 15-94

RECOMMENDATION: Accept proposal as first submitted in 15-94 ROP but revise text in item (3) as follows:

(3) Be a listed electrical circuit ~~protection~~ protective system with a minimum 1-hour fire rating where installed in accordance with the listing requirements.

SUBSTANTIATION: (The panel's statement is to be noted: "No listing presently exists for item 4"). I would like to offer valid technical substantiation that item (4) does indeed exist and why it should be included as a separate item.

There are presently 4 listed manufacturers with such cables found in the UL Building Material Directory under the heading of Fire Resistive Cables. The test methods UL uses to qualify fire resistive cables is either subject 1724 or 2196. Both 1724 and 2196 requires that the circuit integrity of the electrical cables be maintained during a period of fire exposure, and afterwards during exposure to a hose stream.

Although these cables are listed as "Fire Resistive Cables" it's important to have the wording "Be a listed cable to maintain circuit integrity..." as part of their description. The words "fires resistive" are used differently throughout the industry and can be confused with "fire resistant" which are used in the NEC. For example, both plenum and riser cables are described as "having adequate fire-resistant characteristics" but do not maintain circuit integrity.

I would also ask the Code Panel to support a companion comment to Code-Making Panel 1 to accept Proposal 1-113 ROP for the definition of "Circuit Integrity Cable".

The above revision to change the word "protection" to "protective" the way it is listed in the UL Building Material Directory and the added text is needed to make sure the installer is aware of the listing requirements.

PANEL ACTION: Accept in Part.

The panel accepts only the change from "protection" to "protective".

The panel rejects the remainder of the recommendation.

PANEL STATEMENT: Refer to the panel statement on Comment 15-78. Section 110.3(B) requires that listed products be installed and used according to the listing requirements.

15- 80 - (695-6(d), Exception): Reject

SUBMITTER: Lawrence A. Bey, Onan Corp.

COMMENT ON PROPOSAL NO: 15-97

RECOMMENDATION: Reject the proposal.

SUBSTANTIATION: Protection of the conductors has nothing to do with the capacity of the generator set. Conductors are sized and protected according to the load current, in this case a fire pump(s). With regard to short circuit protection of equipment, it is not necessary to repeat, using different words, what is already required by Article 110. The intent of this proposal was more appropriately addressed by the panel action on Proposal 15-87.

PANEL ACTION: Reject.

PANEL STATEMENT: The existing text discusses the protection of the conductors at the load of the motor. The conductors do not need to be overloaded without any protection to the point of unnecessary and premature failure.

(Log #805)

15- 82 - (695-6(e)): Reject

SUBMITTER: David H. Kendall, Carlon

COMMENT ON PROPOSAL NO: 15-98

RECOMMENDATION: This proposal to add Schedule 80 Rigid Nonmetallic Conduit should be accepted.

SUBSTANTIATION: It would have been very easy to test and compare Schedule 80 PVC conduit against Type MI Cable in the Fact Finding Report. That Fact Finding Report would have easily shown the superior physical characteristic of the heavy wall conduit compared to the cable. MI Cable is currently and has been an acceptable wiring method for fire pumps.

The Fact Finding Report utilized the comparison of Schedule of 80 PVC Conduit to a raceway (GRC) with similar superior physical properties. This Fact Finding report was not an attempt to show that Schedule 80 PVC was superior to GRC but to show that it would protect the wiring of a fire pump as well as those wiring methods currently allowed.

PANEL ACTION: Reject.

PANEL STATEMENT: The tests performed have shown the differences between aluminum RMC and RNMC under specific conditions. The proponents of this product have not shown sufficient substantiation to indicate RNMC to be equal or superior to wiring methods that are already permitted. Furthermore the submitter mistakenly refers to the fact finding report as comparing schedule 80 PVC to GRC when in fact it compared Schedule 80 PVC to aluminum RMC.

NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 18

VOTE ON PANEL ACTION:

AFFIRMATIVE: 12

NEGATIVE: 5

ABSTENTION: 1

EXPLANATION OF NEGATIVE:

AMOS: I'm voting against the panel action to reject this proposal. The UL fact-finding report submitted with the proposal provides the entire technical substantiation necessary to support the acceptance of schedule 80 rigid nonmetallic conduit. RMC has, according to the UL fact-finding report; to have appropriate performance for the application, in terms of impact resistance, crush resistance as well as flammability. Aside from being a UL listed product it also provides additional thermal protection to the conductors by preventing heat transmission.

JOHNSON: Tests show that Schedule 80 PVC conduit will protect fire pump wiring as well as currently allowed methods.

GLENN: I am voting against the panel action to reject this comment and the original proposal. The submitter provided adequate documentation with his original proposal in the form of a UL Fact-Finding Report that supports the acceptance of schedule

80 rigid nonmetallic conduit to be installed from the controllers to the pump motors. The panel is still hung up on the physical strength of this material. UL lists Schedule 80 RNMC as being resistant to physical damage and as being acceptable for electrical conduit installations. There is no sound reason for not including schedule 80 rigid nonmetallic conduit for this application.

HIRSCHLER: I oppose the action by the panel. This comment should have been accepted. I reproduce the comments I made at the proposal stage, and which the Technical Correlating Committee considered to be worthy of further consideration as a public comment, together with the comments of Peter Amos, Michael Glenn and John Kovacik).

"The UL fact finding report accompanying the proposal indicates that schedule 80 rigid nonmetallic conduit (RNMC) has appropriate performance for the application, in terms of impact resistance, crush resistance and flammability. The Fact-Finding report compared schedule 80 with rigid metallic conduit (i.e. aluminum conduit), and compares equivalent systems. The added use of grounding conductors in RNMC (not needed for the aluminum conduit) means that a larger outer diameter pipe is required to contain 3 circuit conductors of 1/0 AWG size; thus 40% conductor fill means a 1 1/2 inch diameter RMC conduit and a 2 inch diameter RNMC conduit. See details of results:

Impact test: for both RMC and RNMC the conduit protected the conductors from shorts when a 75 pound weight was dropped from up to a 6 ft height (with the larger diameter, compared to a listing requirement of 4 ft for RNMC) or when the weight was dropped from up to 1.5 ft (with the smaller diameter, compared to a listing requirement of 1.25 ft for RNMC).

Crush test: both RMC and RNMC the conduit protected the conductors from shorts when a crushing force was applied, with the crushing force required to cause a short being higher for the smaller size of RNMC than for that of RMC, while the opposite was true for the larger diameters, indicating comparable results..

Flammability: the smaller sizes of RMC and RNMC protected the conductors to exactly the same time, ca. 3 min. The flammability test on the larger diameter conduit was the single test for which there was a significant difference in circuit protection, with RMC being superior, but even there RNMC gave 5-12 min circuit integrity, while 4 of the 6 RMC tests gave 10-16 min circuit integrity, on exposure to a 60 kW gas burner flame.

Thus, schedule 80 rigid nonmetallic conduit is a UL-listed product, which has been shown in tests to be sufficiently resistant to physical damage for the application. It is also capable of preventing the heat transmission which occurs with metal conduit and which can destroy the conductors. The material used for schedule 80 rigid nonmetallic conduit is PVC, which has excellent fire performance, including low propensity for ignition and very low heat release once ignited. Moreover, supply conductors are required to be routed outside the buildings, or behind 2 inches of concrete or behind a fire rated wall, with a 1 hour rating."

The panel statement is another example of a decision made without considering the facts: it states that "The proponents of this product have not shown sufficient substantiation to indicate RNMC to be equal or superior to wiring methods that are already permitted", when the fact finding report (and my comment) both showed that RNMC is equivalent or superior in all aspects to the permitted RMC or aluminum conduit. Moreover, as the submitter explains, the RNMC has significantly superior physical characteristics to another permitted wiring method, namely MI cable. Also, as stated by both Michael Glenn and John Kovacik in their negative comments at the proposal stage, the question is not whether RNMC is equal or superior to GRC, since most other accepted wiring methods are also not equal or superior to GRC, but whether it is equal to at least one of the acceptable wiring methods, and the information presented shows that to be the case. Finally, as stated by Peter Amos in his negative comments at the proposal stage, "there is no reason to continue suppressing the use of a proven product, simply because it's new."

KOVACIK: I am voting against the panel action to reject proposal 15-98. As stated in my negative ballot for 15-98 in the ROP, the submitter has demonstrated that Schedule 80 RNMC is equivalent to at least one of the raceways presently allowed by 695-6(e). The submitter has provided adequate documentation to support acceptance of his proposal. The panel statement lacks adequate technical substantiation to justify rejection of the proposal.

EXPLANATION OF ABSTENTION:

BOYER: See my Explanation of Abstention on Comment 15-25.

(Log #806)

15- 83 - (695-14(e)): Reject

SUBMITTER: David H. Kendall, Carlon

COMMENT ON PROPOSAL NO: 15-111

RECOMMENDATION: This proposal to add Schedule 80 Rigid PVC Conduit should be accepted.

SUBSTANTIATION: It would have been very easy to test and compare Schedule 80 PVC conduit against Type MI Cable in the Fact Finding Report. That Fact Finding Report would of easily shown the superior physical characteristic of the heavy wall conduit compared to the cable. MI Cable is currently and has been an acceptable wiring method for fire pumps.

The Fact Finding Report utilized the comparison of Schedule of 80 PVC Conduit to a raceway (GRC) with similar superior physical properties. This Fact Finding report was not an attempt to show that Schedule 80 PVC was superior to GRC but to show that it would protect the wiring of a fire pump as well as those wiring methods currently allowed.

PANEL ACTION: Reject.

PANEL STATEMENT: The tests performed have shown the differences between aluminum RMC and RNMC under specific conditions. The proponents of this product have not shown sufficient substantiation to indicate RNMC to be equal or superior to wiring methods that are already permitted. Furthermore the submitter mistakenly refers to the fact finding report as comparing schedule 80 PVC to GRC when in fact it compared Schedule 80 PVC to aluminum RMC.

(Log #2145)

15- 84 - (695-14(f) (New)): Reject

SUBMITTER: James Conrad, Rockbestos-Surprenant Cable Corp.

COMMENT ON PROPOSAL NO: 15-114

RECOMMENDATION: Accept Proposal 15-114 ROP but revise text as follows:

(f) Generator Control Wiring Methods. Control conductors installed between the fire pump transfer Switch and the ~~Back up~~ standby generator supplying the fire pump during normal loss shall be kept entirely independent of all other wiring. The wiring shall be stranded wire only and be protected to resist potential damage by fire or structural failure. They shall be permitted to be routed through a building(s) using one of the following:

1) Be encased in a minimum of 50 mm (2 in.) of concrete

2) Be an electrical circuit protective system with a minimum 1-hour fire rating where installed in accordance with the listing requirements

3) Be a listed "CI" cable installed in a metal raceway

SUBSTANTIATION: The above format is easier to read and in Section 695-14(d) the wiring between the controller and a diesel engine are required to be stranded. The same conditions exist between the transfer switch and a standby generator thus requiring stranded conductors.

Type "CI" cable is currently being used in Article 760 to meet the survivability requirements for fire alarm cable. The "CI" marking is a suffix that is attached to a cable after it has passed the UL 2196, "Standard for Tests of Fire Resistive Cables". (See companion comment on 1-114 ROP for definition of "CI" cable).

An electrical circuit protective system is tested to the same UL fire test with the exception of the water exposure portion of the test. The electrical circuit protective system is subjected to a hose stream test and the "CI" cable is subjected to a fog nozzle spray.

Both wiring methods meet the requirements of survivability when exposed to fire, but the electrical circuit protective system must be installed with the systems listing requirements that can be very difficult to meet. On the other hand, the "CI" cable was tested as a stand-alone product thus not having the same restrictions as a

system listing. This alone would make meeting the survivability requirements much easier and much more affordable.
PANEL ACTION: Reject.
PANEL STATEMENT: The word "standby" is already part of the text.

There has not been any technical substantiation to require stranded wire or for the addition of item 3).

There has been no substantiation to delete some of the requirements of the wiring methods now allowed.

ARTICLE 700 — EMERGENCY SYSTEMS

(Log #2398a)

15- 85 - (700(xx)): Reject
SUBMITTER: Jan Zemplenyi, Bel Red Amulatory Surgical Center
COMMENT ON PROPOSAL NO: 15-115
RECOMMENDATION: All facilities which provide sedation or general anesthesia shall be equipped with a back-up power mechanical generator or high-grade battery system with sufficient power and duration to assure the ability to conclude any operative procedure safely.
SUBSTANTIATION: The following is the contents of a letter I sent to Mr. Mayer Zimmerman of the Health Care Financing Administration on September 8, 2000:

It is clear to me that the amount of necessary kilowatts of back-up power depends on the size of the facility, and also on the time necessary for the completion of any procedures in progress when the black-out occurs. In our facility, we do not need large amounts of back-up power supplied for many hours in order to complete safely any of my operations. Our patient monitors are equipped with two-hour internal battery backup. Thus, in the first two hours of a blackout, we only need continuous power for the operating room lights and brief bursts of interrupted power for the electrocautery. Furthermore, the requirements are not different whether we use general or I.V. sedation anesthesia because the anesthesia machine does not use electrical power. The power system we have provides more than two hours of backup power so that I am not limited to only a two-hour duration. In my eleven years of performing office-based ambulatory surgery, I needed back-up power only once, and the Sola battery system we currently have worked out very well. We also test our battery system monthly. It functions instantaneously, and it provides us with the supply of clean current needed for our equipment.

In my recent research into the subject of backup power, I came across several battery systems including the Concorde batteries, which are used by the military and civil aviation industry for emergency power for their critical systems. Clearly, I think that my critical power requirements do not exceed those of F/A-18 or an F-117 Stealth fighter aircraft. In fact, as compared to a gasoline or diesel generator, and appropriately sized battery/inverter system provides a source of quiet, clean, reliable, and instantaneous power. Modern batteries are extremely reliable and maintenance free, whereas a generator needs to be "exercised and loaded" about once per month in order to be reliable. With a generator, there are other issues related to noise, storage and flammability of fuel. In addition, the quality of the electrical current generated can be deleterious to the electronic equipment since the waveform is not uniformly sinusoidal. In contrast, modern high-quality batteries and inverter systems provide clean sine wave, constant instantaneous current.

In summary, I feel that the requirement to retrofit my small ambulatory surgical center with a mechanical generator (prime mover) equipped with a transfer switch, is an expensive, burdensome requirement and a hardship. In my opinion, it will not add in any way to the safety of my surgical patients. I also know that, in general, certain modern battery/inverter systems can provide a superior alternative to generators, especially in instances when the total power requirements are relatively small and rather clearly defined. I strongly believe that further rational modification to the current rules is in order, especially within view of new developments in battery power technology.
PANEL ACTION: Reject.
PANEL STATEMENT: The requirements proposed do not belong in Article 700. These requirements of emergency power are appropriate in Article 517 and are already covered in NFPA 99.

15- 86 - (700-1(b), FPN No. 3): Reject
SUBMITTER: Lawrence A. Bey, Onan Corp.
COMMENT ON PROPOSAL NO: 15-115
RECOMMENDATION: Delete ~~fire pumps~~ from FPN No. 3 of 700-1 add fire pumps to FPN of 701-2.
SUBSTANTIATION: If the committee statement is correct, to be consistent at least the fine print notes of the scope statements in Article 700 and 701 should be changed.
PANEL ACTION: Reject.
PANEL STATEMENT: Fire pumps need to remain in the FPN of 700.1 since it is a good example of the requirement of a needed emergency power system as opposed to a legally required standby system.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 19
VOTE ON PANEL ACTION:
AFFIRMATIVE: 18
NOT RETURNED: 1 Kakalec
COMMENT ON AFFIRMATIVE:
KOVACIK: In further support of the panel statement, I would like to add that the text of FPN No. 3 of 700-1 is correctly worded in that emergency systems may provide power to a fire pump but are not required to.

(Log #1714)

15- 87 - (700-4): Accept in Principle
SUBMITTER: Dan Chisholm, Healthcare Circuit News
COMMENT ON PROPOSAL NO: 15-120
RECOMMENDATION: I urge the Panel to accept the original proposal without any changes
SUBSTANTIATION: The committee stated in their rejection that "... not all jurisdictions have adopted NFPA 110 and that not all requirements are applicable." I do not think this is true by virtue of the chart I have provided that shows NFPA 70 (Article 517), NFPA 99, NFPA 101 and the Joint Commission on Accreditation of Healthcare Organizations have directly or indirectly referred to NFPA 110 by reference for all maintenance procedures. In addition, all authorities having jurisdiction should be using one of these standards, even if by default, because these are the only existing standards that specifically address generator maintenance.

I am a little confused by the Panel's reaction to this proposal. In rejecting another of my proposals (15-116, Log #1705) it was stated that, "The proposed exception would circumvent the approval/listing process accepted universally." How can you approve a "universal" listing standard for the manufacture of generator sets, and yet give each authority having jurisdiction the ability to use any standard they choose for the maintenance of these same sets?

I urge you to vote to accept my original proposal, as this would eliminate a lot of confusion and "folk lore" presently being used for the maintenance of sets, which is the cause of the majority of EPS failures. Having been a generator set contractor for many years, I know this to be a fact, and not one generator maintenance contractor in the country would disagree. We have seen cases where NFPA 110 was not followed and people lost their lives.

Note: Supporting material available for review at NFPA Headquarters.
PANEL ACTION: Accept in Principle.
At the end of 700.4, add the following FPN: "For testing and maintenance procedures of Emergency Power Supply Systems (EPSSs), see NFPA 110, Standard for Emergency and Standby Power Systems".
PANEL STATEMENT: The panel agrees with the submitter that this information would be helpful in directing users to the appropriate standard for testing and maintenance. The panel feels this information is better served as a FPN.

In order to be enforceable, the particular code has to be adopted by the local jurisdiction.

SUBMITTER: Bruce Reynolds, State of Washington
COMMENT ON PROPOSAL NO: 15-123
RECOMMENDATION: Delete following text:
Transfer equipment and electric power production systems installed to permit operation in parallel with the normal source shall meet the requirements of Article 705.
SUBSTANTIATION: This text should appear only in Article 702. The transfer equipment for Emergency Systems Article 700 and Legally Required Standby Systems Article 701 needs to be kept simple and pure and dedicated for just these systems. As working in electrical plan review, we are seeing Emergency Systems becoming more and more complex. This has created several situations when maintenance personnel have brought entire electrical systems off line and could not figure out how to bring them back. In one case, this was a hospital with a co-generation system. Not only did the co-generation system go down but also the emergency system. This was while surgeries where taking place. Luckily ,no loss of life occurred. Let the Optional Standby Systems be used for all other uses and leave the transfer equipment for required systems remain dedicated for just these uses.
PANEL ACTION: Reject.
PANEL STATEMENT: There is no way to prevent unqualified personnel from removing electrical power from a facility. The statement needs to remain for the safety of the public and line workers.

(Log #2293)

15- 90 - (700-9(d)(1), Exception): Reject
SUBMITTER: Jim Milne, General Cable Pytrotenax
COMMENT ON PROPOSAL NO: 15-128
RECOMMENDATION: This Proposal should be Accepted in Principle.
Add the following Exception following Section 700-9(d)(1)(f). This Exception applies to 700-9(d)(1).
Exception: Where an internal combustion engine is used as the prime mover of a generator set in accordance with 700-12(b)(2), the feeder-circuit wiring shall meet one of the following conditions:
(a) Be installed within buildings that are fully protected by an approved automatic fire suppression system
(b) Be a listed electrical circuit protective system with a minimum 2-hour fire rating
(c) Be protected by a listed thermal barrier system for electrical system components with a minimum 2-hour fire rating
(d) Be protected by a fire-rated assembly listed to achieve a minimum fire rating of 2 hours
(e) Be embedded in not less than 125 mm (5 in.) of concrete
(f) Be a cable listed to maintain circuit integrity for not less than 2 hours when installed in accordance with the listing requirements
SUBSTANTIATION: NEC Section 700-12(b)(2) requires that "Where internal combustion engines are used as the prime mover, an on-site fuel supply shall be provided with an on-premises fuel supply sufficient for not less than 2 hours full-demand operation of the system. Where power is needed for the operation of the fuel transfer pumps to deliver fuel to a generator set day tank, this pump shall be connected to the emergency power system."
Since the fuel transfer pumps are required to be connected to the emergency power system, then the emergency power system must be capable of operating for 2 hours to comply with the requirement "for not less than 2 hours full-demand operation of the system." A 1 hour rating on the emergency system does not comply.
Addition of this exception will eliminate the conflict that currently exists between Sections 700-9(d)(1) and 700-12(b)(2).
The Exception shown above also incorporates revisions made by the Panel in Proposals 15-124a and 15-125.
The International Building Code, 403.10.1.1 also requires sufficient fuel to keep the generator operational for 2 hours.
NFPA 110, 5-2.1 and the International Building Code, 403.10.1 both require that the generator must be installed in a separate room and this "room shall have a minimum 2-hour fire rating".
The emergency system consists of hundreds or, in many cases, thousands of feet of wiring routed through a building, so the potential exposure to fire is much greater than that of the emergency generator. If the wiring is lost, the entire emergency system is rendered worthless.
Note: Supporting material is available for review at NFPA Headquarters.
PANEL ACTION: Reject.
PANEL STATEMENT: The substantiation of increasing the feeder circuit wiring to two hours has nothing to do with the requirement of the fuel supply of the prime mover when it is a generator.

(Log #1780)

15- 91 - (700-12(b)(6)and 701-11(b) (5)): Accept in Principle
SUBMITTER: Jim Pauley, Square D Company
COMMENT ON PROPOSAL NO: 15-135
RECOMMENDATION: The panel should reconsider and reject the proposal.
SUBSTANTIATION: As written, the new language would allow a disconnect for a power supply to a building to be located at the generator, but places no restrictions on where the generator is in relation to the building. The generator could be a significant distance away, blocked by obstructions between in and the building (like a fence) or otherwise located in a manner not obvious to occupants of the building. Although the proposer attempted to reduce perceived redundancy in disconnecting means, the language introduces significant safety issues for complete disconnection of power from a building.
Furthermore, the new language is not needed. Since CMP 4 has taken action in 225.31(A) to establish that a building disconnect can be on or within sight of a building, the permission to have a disconnect at/on a properly located generator is already handled.
Although there are special concerns for Article 700 and 701 systems, relaxing the building disconnecting rules and introducing other safety issues is not the direction that should be taken.
PANEL ACTION: Accept in Principle.
Revise the panel action of Proposal 15-135 to read as follows: "Where an outdoor housed generator set is equipped with a readily accessible disconnecting means located within sight of the building or structure supplied, an additional disconnecting means shall not be required where ungrounded conductors pass through the building or structure."
PANEL STATEMENT: This added verbiage will address the submitter's concern and still provide the safety needed.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 19
VOTE ON PANEL ACTION:
AFFIRMATIVE: 18

COMMENT ON AFFIRMATIVE:
FLACH: I voted affirmative with the addition of these words: "Where an outdoor housed generator set is equipped with a readily accessible disconnecting means located within 50 feet and visible from the building or structure supplied, an additional disconnecting means is not required.
Substantiation: To clarify the intent.

(Log #853)

15- 92 - (700-25 Coordination): Accept
SUBMITTER: Larry F. Miller, National Electrical Manufacturers Association (NEMA)
COMMENT ON PROPOSAL NO: 15-136
RECOMMENDATION: The Panel should reject this proposal.
SUBSTANTIATION: The current fine print note in 700-25 was never intended to be enforced. It is design information and not a safety requirement. Section 90-1(a) states that the purpose of this code is the practical safeguarding of persons and property from hazards arising from the use of electricity. Selective coordination of the overcurrent device is not a hazard arising from the use of electricity, it is a design issue to be decided by the engineer.
The panel action on comment 15-122 during the 1999 NEC rejected a similar proposal. The submitter has not presented any new safety information or documentation that would support changing the fine print note to a mandatory requirement.
PANEL ACTION: Accept.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 19
VOTE ON PANEL ACTION:
AFFIRMATIVE: 15
NEGATIVE: 3
NOT RETURNED: 1 Kakalec
EXPLANATION OF NEGATIVE:
FLACH: Proposal 15-136 should not be rejected. This is a safety issue, not a design consideration. The code requires emergency feeder wiring to be protected by a circuit protective system with a minimum 1-hour fire rating, or other protective systems, to enhance the reliability of the emergency system in some assembly occupancies or in buildings that exceed 75 feet in height. These requirements are found in Section 700-9(d).
To improve the reliability of these emergency feeders, coordinated protection of the branch circuit and feeder overcurrent devices should be mandatory. Therefore, I propose the following: New "700-26 Overcurrent Protection Coordination. Fuses and Circuit breakers for emergency circuit overcurrent protection shall be coordinated to ensure selective clearing of fault currents where installed in assembly occupancies of greater than 1000 persons or in buildings above 75 feet in height with any of the following occupancy classes: assembly, educational, residential, detention and correctional, business and mercantile."
(Note: Part of this comment is extracted from Section 700-9(d)).
JOHNSON: The substantiation in the comment is not correct. Coordination is a safety requirement. Without it a fire in an isolated area can cause a fault that will trip the main breaker on the emergency generator and put the entire building in darkness, handicapping evacuation. If coordination is not required, a shunt excited generator can be used without series boost and a fault anywhere in the system will cause the generator voltage to collapse. The generator is not damaged but the building does not have emergency power. Every effort should be made to isolate faulted circuits and keep emergency power on to essential loads. The panel has done exactly the same thing they did in 1997, reversed their position without thinking through the importance of maintaining emergency power as long as possible. They give no reason for changing their position.
KLEIN: 1. I agree with the submitter of Proposal 15-36. Selective coordination of overcurrent devices should be a mandatory code requirement.
2. This issue is related to practical safeguarding more than it is related to design.

(Log #1788)

15- 93 - (700-25): Accept
SUBMITTER: Alan Manche, Square D Co.
COMMENT ON PROPOSAL NO: 15-136
RECOMMENDATION: The panel should reconsider and reject this proposal.
SUBSTANTIATION: The FPN should not be changed to a mandatory requirement. During the 1999 NEC cycle, the panel rejected proposal 15-122, which is nearly identical to this proposal. No further safety concerns are provided in the substantiation only a "customer expectation" concern.
PANEL ACTION: Accept.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 19
VOTE ON PANEL ACTION:
AFFIRMATIVE: 16
NEGATIVE: 2
NOT RETURNED: 1 Kakalec
EXPLANATION OF NEGATIVE:
FLACH: I vote to reject the panel action. See my Explanation of negative vote on Comment 15-92.
JOHNSON: See my Explanation of Negative Vote on Comment 15-92.
COMMENT ON AFFIRMATIVE:
KOVACIK: Although I am voting to support the panel action, I do not agree with the submitter's comment in the substantiation that Proposal 15-136 is nearly identical to rejected Proposal 15-122. Proposal 15-122 was a recommendation to add a requirement for load calculation to 700-5(a). This was considered unnecessary and redundant since this requirement is already located in Chapter 2. Proposal 15-136 recommended that current code text that is informative be changed to mandatory.

(Log #1787)

15- 94 - (700-26): Reject
SUBMITTER: Alan Manche, Square D Co.
COMMENT ON PROPOSAL NO: 15-136
RECOMMENDATION: Revise the panel action in the ROP as follows:
700-26 Coordination. Fuses and circuit breakers for emergency circuit overcurrent protection shall be coordinated to selectively clear fault currents, <u>including ground-faults.</u>
SUBSTANTIATION: I have another comment requesting the original proposal be rejected because this is a design consideration, which I believe is the proper course of action. However, if the panel disagrees and believes there is an electrical safety implication then this comment should be accepted to ensure that all fault conditions are covered.
The submitter's concern of a "built-in blackout" or "insignificant short in the branch circuit" is not addressed by this proposal. A ground-fault is a more likely occurrence than the selective coordination concern of the overcurrent devices. Therefore, if the panel insists this is a safety concern then selective coordination of ground-fault protection must also be required and the panel action would need to be revised to read:
"Without this revision the panel will have added a selectivity requirement and not obtained selectivity under the most likely fault occurrence."
PANEL ACTION: Reject.
PANEL STATEMENT: The submitter's concerns have been resolved by panel action on Comment 15-93.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 19
VOTE ON PANEL ACTION:
AFFIRMATIVE: 16
NEGATIVE: 2
NOT RETURNED: 1 Kakalec
EXPLANATION OF NEGATIVE:
FLACH: I vote against the panel action. See my Explanation of negative vote on Comment 15-92.
JOHNSON: The author is correct. If coordination is required it should also be necessary to coordinate ground fault protection if used. However, only ground fault indication is required and that only on systems over 1000 amperes, see 700-6(d).

ARTICLE 701 — LEGALLY REQUIRED STANDBY SYSTEMS

(Log #1715)

15- 95 - (701-5): Accept in Principle
SUBMITTER: Dan Chisholm, Healthcare Circuit News
COMMENT ON PROPOSAL NO: 15-137
RECOMMENDATION: I urge the panel to accept the original proposal without any changes
SUBSTANTIATION: The committee stated in their rejection that "... not all jurisdictions have adopted NFPA 110 and that not all requirements are applicable." I do not think this is true by virtue of the chart I have provided that shows NFPA 70 (Article 517), NFPA 99, NFPA 101 and the Joint Commission on Accreditation of Healthcare Organizations have directly or indirectly referred to NFPA 110 by reference for all maintenance procedures. In addition, all authorities having jurisdiction should be using one of these standards, even if by default, because these are the only existing standards that specifically address generator maintenance.
I am a little confused by the panel's reaction to this proposal. In rejecting another of my proposals (15-116, Log #1705) it was stated that, "The proposed exception would circumvent the approval/listing process accepted universally." How can you approve a "universal" listing standard for the manufacture of generator sets, and yet give each authority having jurisdiction the ability to use any standard they choose for the maintenance of these same sets?
I urge you to vote to accept my original proposal, as this would eliminate a lot of confusion and "folk lore" presently being used for the maintenance of sets, which is the cause of the majority of EPS failures. Having been a generator set contractor for many ,years I know this to be a fact, and not one generator maintenance contractor in the country would disagree. We have seen cases where NFPA 110 was not followed and people lost their lives.
Note: Supporting material available for review at NFPA Headquarters.
PANEL ACTION: Accept in Principle.
At the end of Section 701.5, add the following FPN: "For testing and maintenance procedures of Emergency Power Supply Systems (EPSSs), see NFPA 110, Standard for Emergency and Standby Power Systems".
PANEL STATEMENT: The panel agrees with the submitter that this information would be helpful in directing users to the appropriate standard for testing and maintenance. The panel feels this information is better served as a FPN.
In order to be enforceable, the particular code has to be adopted by the local jurisdiction.

15- 97 - (701-7(a)): Reject
SUBMITTER: Bruce Reynolds, State of Washington
COMMENT ON PROPOSAL NO: 15-139
RECOMMENDATION: Delete following text:
Transfer equipment and electric power production systems installed to permit operation in parallel with the normal source shall meet the requirements of Article 705.
SUBSTANTIATION: This text should appear only in Article 702. The transfer equipment for Emergency Systems Article 700 and Legally Required Standby Systems Article 701 needs to be kept simple and pure and dedicated for just these systems. As working in electrical plan review ,we are seeing Emergency Systems becoming more and more complex. This has created several situations when maintenance personnel have brought entire electrical systems off line and could not figure out how to bring them back. In one case, this was a hospital with a co-generation system. Not only did the co-generation system go down but also the emergency system. This was while surgeries where taking place. Luckily, no loss of life occurred. Let the Optional Standby Systems be used for all other uses and leave the transfer equipment for required systems remain dedicated for just these uses.
PANEL ACTION: Reject.
PANEL STATEMENT: There is no way to prevent unqualified personnel from removing electrical power from a facility. The statement needs to remain for the safety of the public and line workers.

(Log #2132)

15- 106 - (702-5): Reject
SUBMITTER: Bob Herzig, Bob Herzig and Associates, Inc.
COMMENT ON PROPOSAL NO: 15-155
RECOMMENDATION: Revise text to read as follows:
702-5. Capacity and Rating
"...Optional standby system equipment shall be suitable for the maximum available fault current at its terminals. It shall also have the proper overload rating per the conductor it is protecting. This protection can be provided by branch circuit or supplementary overcurrent protection devices. The user of the optional standby system shall be permitted to select the load connected to the system."
SUBSTANTIATION: The available fault current associated with 7500 Watt generators and below is in the 300-500 ampere range. This much lower fault condition than would be experienced by a utility provided source allows an OCP device with a much lower interrupting rating. The requirement of only allowing branch circuit OCP devices would unnecessarily increase the cost of these devices without providing added safety.
PANEL ACTION: Reject.
PANEL STATEMENT: Proper conductor protection is already covered in Article 240.

15- 108 - (702-6): Accept in Principle
SUBMITTER: Paul Schnackenberg, Gen/Tran Corporation
COMMENT ON PROPOSAL NO: 15-155
RECOMMENDATION: I would like to request that the current wording for Article 702-6 in the 1999 code remain as is with no changes or deletions. 702-6 was written primarily for portable generators where 7500 watts is commonly the maximum size used.
SUBSTANTIATION: It is generally accepted by EGSA (Electrical Generating Systems Association), which Gordon Johnson represents, that generators cannot possibly deliver a fault current exceeding 12 times the output of the generator. For example, if a 7500 watt generator is rated at 30 amps at 250 volts, then 12 X 30 = 360 amps of maximum potential fault current. With this formula in mind, these supplemental breakers would even be capable of handling generators up to 12,500 watts rated at 50 amps at 250 volts. The type of supplementary overload protectors that Gen/Tran has included in its manual transfer switches for 18 years have a short circuit rating of 1000 amps, which is almost three times the available current that the average generator can produce.
UL has mandated, and Gen/Tran has complied, that our label on the product state that the transfer switch be "suitable for generators capable of delivering not more than 1000A rms symmetrical at 250 VAC."
If the phrase "that the generator can deliver" was deleted from Section 702-6, then the homeowner or installer could apply the switch to larger generators, such as 25 kW output, which could deliver more than 1000 A rms.
Mr. Johnson's substantiation states that the equipment must be capable of interrupting the fault current of either the normal or standby source. Our supplemental protective devices are only in the circuit in the "generator" mode. The customer's branch circuit protectors protect the equipment in the "normal" utility mode.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to the panel action and statement on Comment 15-109.

COMMENT ON AFFIRMATIVE:
FLACH: See my Comment on Affirmative on Comment 15-109.

(Log #1014)

15- 109 - (702-6): Accept in Principle
SUBMITTER: Paul Schnackenberg, Gen/Tran Corporation
COMMENT ON PROPOSAL NO: 15-156
RECOMMENDATION: I would like to request that the current wording for Section 702-6 in the 1999 code remain as is, with no changes or deletions. Section 702-6 was written primarily for generators where 7500 watts is commonly the maximum size used in residential applications.
SUBSTANTIATION: Each portion of the submission will be addressed individually. However, first, I question the motive of the submitter and the ultimate reason for submitting the

recommendation in the first place. As you may know, Square D Company is a competitor of Gen/Tran Corporation in the transfer switch market, and it is obvious that Square D has a vested interest in discrediting products that compete with their offering. If Square D is effective at its strategy of trying to eliminate Gen/Tran® products (which, mind you, have been the #1 brand of transfer switches for 18 years) from the market, then they will have succeeded at their mission. However, it is my mission to clarify the meaning of the code to interested parties so as to keep current wording for Section 702-6 in tact.

To provide you with some background, the original compact manual transfer switch design (developed by Gen/Tran Corporation) has been generally available since 1982. Today, two UL listed products that share the same or similar basic design are also available - and incorporate the same types of components in the same type of scheme or arrangement as our products. To date, there are approximately 500,000 Gen/Tran® manual transfer switches that contain roughly 4,000,000 supplemental overcurrent protective devices installed in thousands of homes and businesses throughout the US and Canada. And to date, no complaints about our products have been filed with UL, and we have not had any calls from lawyers or insurance companies claiming that our products were found to be unsafe. Since the company that the submitter represents as well as other large switchgear manufacturers do not make transfer switches with the some scheme as Gen/Tran® products, by cleverly getting the code changed so as to disallow our products Gen/Tran would disappear from the market and the buying public would be forced to purchase only those products offered by the large switchgear manufacturers. With our 18-year track record and outstanding brand reputation, I can safely say that Gen/Tran provides products that the public wants. And if this change were implemented, not only would Gen/Tran lose its market share, but the buying public would lose the products favored by more consumers, more electricians and more inspectors because of its ease of installation and ease of use.

Regarding 240-10. The submitter interprets this article to mean that branch circuit devices should be the only types of circuit protective devices used for all applications and should cover the entire NEC. I will remind you that UL asked me personally to author the proposal to allow supplemental breakers for optional standby systems for the 1993 code. I submitted the substantiation with test records and documentation to show that the wiring scheme incorporated in Gen/Tran® manual transfer switches worked for more than eight years (at the time). As a result, the code panel approved my proposal, and the current version of 702-6 was adopted. Section 702-3 states that unless modified by this Article (702) other articles shall apply. Section 702-6 in its present form modifies the application of other sections (namely 240-10 and 210-20), thus the wording for Section 702-6 must remain in tact as is.

Regarding 210-20 and Overcurrent protection, branch circuit conductors and equipment shall be protected by overcurrent protective devices that have the proper rating. There is no specific mention of full-size branch circuit protective devices, just that the over current protection be adequate for the application in which they are used. In the wiring scheme utilized in Gen/Tran® transfer switches, the branch circuit breakers in the customer's load center provide 10,000 AIC from utility faults. The portable generators generally used in residential applications (typically only up to 7500 watts continuous) cannot produce more than 1000A fault current. Therefore, I question why a 10,000 AIC-rated device should be used when a 1000 AIC-rated device will work just as well?

Included in our submittal for the 1993 code were tests from a UL certified lab. In these tests, the supplemental circuit breakers were subjected to 360 amps of fault current which is 12 times the maximum current of a 7500 watt generator. In our results, all supplemental breakers tripped, and were resettable and reusable afterward.

As a side note, the submitter states some criticism about UL 489 vs. UL 1077, however, I was under the impression that the NEC committee's mission is not to judge what UL standards contain, but rather to write safety into the NEC. With this in mind, and in consideration of our 18-year perfect safety track record, it is evident that the existing Section 702-6 adopted in 1993 adequately allows for the wiring scheme and supplemental protection incorporated in our Gen/Tran® manual transfer switches. Therefore, no changes, deletions or modifications are needed for 702-6 at this time.

PANEL ACTION: Accept in Principle.

Revise the current second paragraph of Section 702-6 of the 1999 code to read as follows:

"Transfer equipment, located on the load side of branch circuit protection, shall be permitted to contain supplementary overcurrent protection having an interrupting rating sufficient for the available fault current that the generator can deliver. The supplementary overcurrent protection devices shall be part of a listed transfer equipment."

PANEL STATEMENT: The panel action addresses the submitter's intent while addressing the safety concern by adding the requirement for listing the equipment.

NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 19

VOTE ON PANEL ACTION:

AFFIRMATIVE: 18

NOT RETURNED: 1 Kakalec

COMMENT ON AFFIRMATIVE:

BOYER: NEMA understands that the language accepted by the Panel requires the supplemental protection be on the load side of a branch circuit overcurrent device regardless of the source of supply.

FLACH: I vote for the panel action with the addition of this sentence at the end of the panel action statement: "Generators connected to this transfer equipment shall not exceed 7.5 kVA 120/240 volts single-phase."

Substantiation: It is necessary to limit the generator size because of the 10W interrupting capacity of supplemental overcurrent protection devices.

(Log #1209)

15- 110 - (702-6): Accept in Principle

SUBMITTER: Neil A. Czarnecki, Reliance Controls Corporation

COMMENT ON PROPOSAL NO: 15-155

RECOMMENDATION: Do not change any of the wording in 702-6 from the text as it exists in the 1999 NEC.

SUBSTANTIATION: Any system should and must be capable of interrupting the fault current supplied to it. Placing any further requirements on interrupting performance is unnecessarily restrictive. As small portable generators cannot produce more than 350 amps of fault current, UL 1077 supplemental protectors rated at 100 AIC are uniquely and exactly suitable. Requiring a UL 489 device rated at 10,000 AIC does not serve to further enhance the public safety, but rather is nothing more than "specmanship".

PANEL ACTION: Accept in Principle.

PANEL STATEMENT: Refer to the panel action and statement on Comment 15-109.

15- 111 - (702-6): Accept in Principle

SUBMITTER: Neil A. Czarnecki, Reliance Controls Corporation

COMMENT ON PROPOSAL NO: 15-156

RECOMMENDATION: Do not change any of the wording in 702-6 from the text as it exists in the 1999 NEC.

SUBSTANTIATION: Any system should and must be capable of interrupting the fault current supplied to it. Placing any further requirements on interrupting performance is unnecessarily restrictive. As small portable generators cannot produce more than 350 amps of fault current, UL 1077 supplemental protectors rated at 1000 AIC are uniquely and exactly suitable. Requiring a UL 489 device rated at 10,000 AIC does not serve to further enhance the public safety, but rather is nothing more than "specmanship".

The substantiation cited in this proposal is in dispute in the following areas:

a. Section 702-5 states, "Optional standby system equipment shall be suitable for the maximum available fault current at its terminals." As small portable generators (<10,000 watt) cannot produce more than 350 amps of fault current, UL 1077 supplemental protectors rated at 1000 AIC are suitable. Requiring a UL 489 device rated at 10,000 AIC does not serve to further enhance the public safety, but rather is nothing more than "specsmanship".

b. Section 702-6 does not supercede Section 240-10, since the utility-derived circuits are still protected by branch-circuit protectors suitable for the maximum available fault current of the utility mains.

c. Utilizing supplemental protectors to protect circuits fed by a standby generator does not compromise protection. Mr. Manche's opinion of the existence of a safety hazard is just that, an unverified and unsubstantiated opinion. The verified fact is that Reliance Controls Corporation has built and sold over 1/4 million transfer switches with over 2 million generator-supplied circuits protected

by supplemental protectors. In the 18 years the product has been on the market, none of the supplemental protectors have failed to perform properly. There is no evidence to indicate that changing to UL 489 devices will enhance the public safety.

d. Mr. Manche infers that, because there is no UL follow-on testing required of UL 1077 supplemental protectors, they are of lesser quality than UL 489 breakers, yet there exists no factual evidence to support this claim. To suggest that all follow-on tested protectors are of good quality and all non-follow-on tested protectors are of poor quality is a classic error in logic. There are certainly poor quality UL 489 protectors, as is evidenced by the substantial number of times UL suspends the listings of UL 489 manufacturers. Similarly, personal injury and product liability claims would certainly eliminate any manufacture of poor quality UL 1077 devices.

e. Mr. Manche states that, because UL 1077 supplemental protectors are not required to perform within predetermined overload trip characteristics, they "may not properly protect the branch circuit conductors from an overload condition". In fact, the published trip-time curves of supplemental protectors show that, up to the available fault current of the generator, they actually trip much faster (2 to 3 times faster) than UL 489 breakers (See chart I have provided). This would indicate the UL 1077 devices actually protect better than UL 489 devices in generator-supplied app;locations, and thus, changing to UL 489 devices would serve to degrade, not enhance, the public safety.

f. Mr. Manche states that UL 1077 devices have smaller spacings than UL 489, but fails to state why. In fact, the spacings required in UL 1077 correspond to the spacings required for all other 120/240 volt residential and light commercial equipment. The reason for larger spacings on UL 489 devices is to prevent restrikes occurring when the device attempts to interrupt high fault currents. Since the generator cannot produce high fault currents, such a requirement is unnecessary. The reason for larger spacings has nothing to do with "pollution" levels, as Mr. Manche states. If it did, light switches and outlets would require UL 489 spacings as well.

(Log #1211)

15- 112 - (702-6): Reject
SUBMITTER: Neil A. Czarnecki, Reliance Controls Corporation
COMMENT ON PROPOSAL NO: 15-157
RECOMMENDATION: Do not change any of the wording in 702-6 from the test as it exists in the 1999 NEC.
SUBSTANTIATION: It is inappropriate to add the underlined paragraph to 702-6. The effect of doing so is to create a "circular logic trap", wherein 702-6 would require a standby backup generator and manual transfer switch to comply with 705 and 705-40 would require manual transfer switches to be automatic. Since Article 705 is intended for electrical power systems which operate in conjunction with the utility mains (known as "synchronous parallel or cogeneration"), and since the majority of backup power installations cannot run in synchronous parallel, amending 702-6 to also require compliance to 705 is simply incorrect.
PANEL ACTION: Reject.
PANEL STATEMENT: The requirements of Article 705 are specified so as to prevent mishap in the event the electrical backup power is wired in parallel.

(Log #1670)

15- 113 - (702-6): Accept
SUBMITTER: Jeffrey F. Morin, MBNA New England
COMMENT ON PROPOSAL NO: 15-158
RECOMMENDATION: Delete "permanently installed".
The change will read:
"Transfer equipment shall be required for all standby systems subject to the provisions of this article and for which an electric-utility supply is either the normal or standby source."
SUBSTANTIATION: As stated in Mr. Hartwell's substantiation of Proposal Number 15-158, an ever-increasing number of consumers are installing Optional Standby Systems. These standby systems consist of those that are permanently installed in their entirety, including prime movers, and those that are arranged for a portable alternate power supply (ROP 15-147).

Article 90, Section 90.1 states that "The purpose of this code is the practical safeguarding of persons and property from the hazards arising from the use of electricity."

Optional Standby Systems, in which portable prime movers are used, generally are installed in residential situations by untrained, unqualified persons. None the less, the same arguments that Mr. Hartwell cites for putting utility line crews at risk is even more significant where the prime mover is a portable alternate power supply.

Removing the words "permanently installed", also recommended by Mr. Flach in his "comment on affirmative" of ROP 15-158 will help 702.6 meet the intent of Article 90.

See supporting Utility Company documentation.

15- 114 - (702-6): Reject
SUBMITTER: Alan Manche, Square D Co.
COMMENT ON PROPOSAL NO: 15-156
RECOMMENDATION: The panel should continute to accept this proposal.
SUBSTANTIATION: Understanding the panel is likely to receive comments on this proposal, a few points should be reemphasized from the original substantiation. Utilizing supplementary protection as the branch circuit protector compromises the protection of the branch circuit and introduces an unnecessary safety hazard.

UL 1077 outlines the requirements applicable to supplementary protectors intended for use as overcurrent, or over- or under-voltage protection within an appliance or other electrical equipment where branch circuit overcurrent protection is already provided. Conditions of Acceptability are placed on supplementary protectors that must be considered for each appliance in which they are installed. Keep in mind supplemental protectors evaluated to UL 1077 are not required to perform within predetermined overload trip characteristics, which means a supplementary protector may not properly protect the branch circuit conductors from an overload condition.

UL has also issued a bulletin on August 18, 2000 for UL 1008, Transfer Switches, that recognizes the concern addressed in this proposal:

"20B Supplementary Overcurrent Protectors (Added Section 20B effective (24 months after date of publication) 20B.1. When a supplementary overcurrent protector is employed, it shall be located on the load side of the branch circuit overcurrent protector device."

Supplemental protectors installed in a panel as the branch circuit device compromises the safety of the branch circuit conductors and panelboard and is a violation of Section 240-10.
PANEL ACTION: Reject.

(Log #2271)

15- 115 - (702-6): Accept in Principle
SUBMITTER: James Allison, Mechanical Products Co.
COMMENT ON PROPOSAL NO: 15-155 and 15-156
RECOMMENDATION: Make no changes to Section 702-6, Transfer Equipment.
SUBSTANTIATION: The reasoning noted in Proposal 15-156 and implied by Proposal 15-155 against the use of supplementary protectors (UL 1077) in transfer equipment is not totally valid as noted below:

1. Conditions of acceptability and follow-up testing - The fact that there are associated conditions of acceptability for supplementary protectors does not mean they must be eliminated from applications. A condition of acceptability for a supplemental protector in a transfer system could be an established maximum fault current rating to be matched with generator capacity. While there is no follow-up testing, these devices are subjected to follow-up validation of construction by the agencies. The field experience of Mechanical Products, covering millions of units, indicate there are virtually no problems with supplementary protectors in these applications.

2. Calibration - It is suggested by proposal 15-156 that a UL489 device meets a precise trip curve. The 489 requirements of 100% hold, 135% trip and a 200% time of 30 seconds maximum are not extraordinarily precise. In fact, the performance of many UL1077 approved products surpasses these limitations. Again, if these limits are deemed necessary, only UL1077 devices meeting them could be used, but this should not eliminate all such devices from consideration.

3. Supplementary protector short circuit ratings - The short circuit ratings for a UL1077 device do not have the same meaning as a circuit breaker's AIC (amps interrupt capacity) both in ability to clear the circuit and in operational performance following a fault. But fault currents from standby power devices only range up to a few hundred amps and could be evaluated under such conditions for these applications. Under the definition of Section 702-2 where as "life safety does not depend on the performance of the system", an open, inoperable protector after short circuit should be acceptable.

4. Spacings - In general, spacing requirements for 1077 devices are lower than 489 products. Greater spacings are required in 489 devices mainly for two reasons - A) tracking and other problems associated with the high interrupts they are required to meet and B) high line transients that they may be subjected to. Neither of these conditions are associated with standby power systems. And UL1077 devices have proven in application to meet performance requirements for this category of industrial equipment.

Conclusions: Supplementary protectors have a proven track record of being capable of handling the protective functions related to both transfer systems and the generators of standby systems provided they are tested under applicable overload and short circuit conditions. The proposed changes (15-155 and 15-156) to Section 702-6 to require the use of UL489 protective devices will substantially impact prices consumers will pay for these end products, while offering no actual improvement to enhance public safety.

16- 14 - (725 Title): Accept
SUBMITTER: Irving Mande, Edwards Systems Technology
COMMENT ON PROPOSAL NO: 16-31
RECOMMENDATION: Reject the proposal.
SUBSTANTIATION: In his substantiation, the submitter of this proposal states that the recommended changes to the title are intended to coordinate with the deletion of power-limited sources from Section 725-21 (Proposal 16-43). If my comment on 16-43 is accepted, this comment should also be accepted.
Also, changing "circuits" to "systems" is not appropriate because the vast majority of Class 1, 2 and 3 applications do not include a listed system.
The submitter of this proposal makes no claim that Class 1 Power-limited Circuits are unsafe or present any type of hazard. His only reason for recommending that these types of circuits be deleted is that they are not needed because no one uses them. For evidence, he claims that there are no listed products that meet the requirements of Section 725-21(a). That is not true.
The only requirement for a Class 1 power-limited circuit in Section 725-21(a) is that they be supplied from a source that has a rated output of not more than 30 volts and 1000 volt-amperes. Unlike the requirements in Section 725-41(a) for Class 2 and 3 power sources, which are required to be listed as either Class 2 or Class 3, there is no such requirement for Class 1 power-sources. As a result, UL does not list them as Class 1 and would respond to an inquiry by saying that they have no Class 1 products listed. However, they do have listed products that meet the requirements for Class 1 products.
The decision whether to install these products as Class 1 power sources is not made by the manufacturer; it is made by the installer. Deleting Class 1 power-limited circuits from the code will unnecessarily deny them the option of taking advantage of the benefits provided by using Class 1 wiring methods.
PANEL ACTION: Accept.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 22
VOTE ON PANEL ACTION:

16- 15 - (725, 760, 800, 820 and 830): Reject
SUBMITTER: Irving Mande, Edwards Systems Technology
COMMENT ON PROPOSAL NO: 16-29
RECOMMENDATION: Reconsider the panel action and accept this proposal.
SUBSTANTIATION: The panel statement indicates that the panel did not fully understand the intent of this proposal. The panel is correct in stating that additional marking is not needed to achieve circuit identification. The cables identified in the panel statement can be used to achieve that purpose. The purpose of this proposal is to achieve cable identification and not circuit identification.
Since it is the intent of this code to permit communication cables (CM) to be used as a substitute for CL2, CL3, FPL, CATV and BL cables in addition to its use for communications circuits, the proposed additional marking is needed to make installers and inspectors aware of the cable's permitted multiple uses.
PANEL ACTION: Reject.
PANEL STATEMENT: Changing the marking on communications cables without any changes in use requirements is a burdensome and unnecessary change.

(Log #1123)

16- 16 - (725): Reject
SUBMITTER: Paul Dobrowsky, Holley, NY
COMMENT ON PROPOSAL NO: 16-30
RECOMMENDATION: The proposal should be accepted.
SUBSTANTIATION: The definition of premises wiring uses the term "control wiring" and many other articles use the term "control circuit" to describe these types of circuits. Article 430 uses the term "motor control circuit" without the word remote. A control circuit at its connection point to a control transformer or Class 2 power supply inside an enclosure doesn't seem remote. The requirements applicable to control circuits do not change based on how far they are from device, equipment, or system being controlled. If the control circuit is an integral part of the equipment, it will be covered by the product standard. A corresponding proposal has been submitted to Code-Making Panel 1.
PANEL ACTION: Reject.

PANEL STATEMENT: The Panel 16 reaffirms its original reason for rejection as documented in the panel statement of Proposal 16-30.

16- 18 - (725-2 Abandoned Cable (New)): Accept in Principle
SUBMITTER: Gerald Lee Dorna, Belden Wire & Cable Co.
COMMENT ON PROPOSAL NO: 16-32
RECOMMENDATION: The definition of "Abandoned Cable" should be the same here as what we accepted in Proposal 16-273. It should be:
"Cable that is neither terminated at ~~both ends, at a connector or other~~ equipment, nor identified for future use with a tag."
This is the same wording we accepted for Proposal 16-273.
SUBSTANTIATION: The reason we took out the reference to connectors in Proposal 16-273 is because CATV cable usually has connectors attached. It was our concern that CATV cables would have connectors attached and then would not fall under the definition the panel had accepted in principal. If we make the definition the same as I have suggested above then it will make it irrelevant on whether the cable has connectors or not. I can foresee someone using the fact that the cable has a connector on it, therefore it does not fall under "abandoned cable" and does not need to be removed.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-21.

16- 19 - (725-2, Abandoned Cable): Accept in Principle in Part
SUBMITTER: Technical Correlating Committee on Signaling Systems for the Protection of Life and Property
COMMENT ON PROPOSAL NO: 16-32
RECOMMENDATION: Revise the proposed definition of abandoned cable to read as follows:
"Cable that is neither terminated at equipment, nor identified for future use with a dated tag."
SUBSTANTIATION: The definition proposed for 820-2 by the Panel Action of Proposal 16-273 is clear and concise and should be used consistently in all Articles. This proposed definition has been modified in the above recommendation to add the word "dated" before the word "tag." The tag should be dated so the authority having jurisdiction can determine the date on which the cable was designated for future use. This will establish a means to allow the decision of abandonment to be re-evaluated periodically if the authority having jurisdiction so desires.
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-21. Panel statement on Comment 16-246 includes the explanation for the rejected part.

(Log #1854)

16- 21 - (725-2): Accept in Principle
SUBMITTER: Robert W. Jensen, dbi-Telecommunications Infrastructure Design
COMMENT ON PROPOSAL NO: 16-32
RECOMMENDATION: New wording:
Abandoned Cable. Installed cable that is neither terminated at both ends at equipment, nor identified for future use with a tag.
SUBSTANTIATION: BICSI added the word installed to show that the cable needs to be installed and not in the installers truck. We retained "terminated at both ends" because fire alarm cable is typically terminated at both ends at equipment when it is in use (i.e., when not abandoned). We removed the term "connectors" since the cable is typically connected directly to equipment.
PANEL ACTION: Accept in Principle.
Revise the recommendation to read as follows:
"Abandoned Class 2, Class 3 and PLTC Cable. Installed Class 2, Class 3 and PLTC cable that is not terminated at equipment and not identified for future use with a tag."
PANEL STATEMENT: The revised text expresses the intended definition and complies with the Manual of Style.

(Log #1572)

16- 22 - (725-2-Abandoned Cable): Accept in Principle
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-32
RECOMMENDATION: Revise text to read as follows:
Abandoned Cable: Cable that is <u>not</u> ~~neither~~ terminated at both ends, ~~at a connector or other~~ <u>not connected to</u> equipment, <u>or not</u> ~~nor~~ identified for future use with a tag.
SUBSTANTIATION: The term "terminated at a connector" may result in cables being left in place as many cables come with connectors or the installer could add crimp connectors and leave the cables in place. The present language can be easily misunderstood: does the cable have to be terminated and tagged, or is it a choice?
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-21.

VOTE ON PANEL ACTION:
AFFIRMATIVE: 22

(Log #1579)

16- 27 - (725-3(b)): Accept in Principle in Part
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-80
RECOMMENDATION: Revise text to read as follows:
Spread of Fire or Products of Combustion. Installations in hollow spaces, vertical shafts, and ventilation or air-handling ducts shall be made so that the possible spread of fire or products of combustion will not be substantially increased. Openings around penetrations through fire resistance-rated walls, partitions, floors, or ceilings shall be firestopped using approved methods to maintain the fire resistance rating.

Abandoned cables not intended for future use shall not be permitted to remain.

FPN: Directories of electrical construction materials published by qualified testing laboratories contain many listing installation restrictions necessary to maintain the fire-resistive rating of assemblies where penetrations or openings are made.
SUBSTANTIATION: This definition under the section entitled "Spread of Fire or Products of Combustion" is not consistent throughout the Code. This comment uses language from ROP 16-250 [850-52(B)] to provide a consistent requirement throughout the code.

The same comment is being made for the following sections:
640-3A (ROP 16-1a)
645-5D6 (ROP 12-106)
645-5D6 (ROP 12-106)
760-3A (ROP 16-144)
770-3A (ROP 16-176)
820-3A (ROP 16-313)
820-52B (ROP 16-311)
830-3A (ROP 16-364)
830-58B (ROP 16-368)
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: The panel accepts in principle the statement regarding abandoned cables. Refer to panel action on Comment 16-83. This satisfies the submitter's concerns.

The current reference to 300-21 satisfies the balance of the comment, which is rejected. That portion of the comment repeats the text of 300-21.

16- 29 - (725-5): Reject
SUBMITTER: Glenn W. Zieseniss, Crown Point, IN
COMMENT ON PROPOSAL NO: 16-38
RECOMMENDATION: Change the "Accept in Principle" to "Reject".
SUBSTANTIATION: I agree with Mr. Egesdal's and Mr. Speer's negative vote and comment on Proposal 16-192. This proposal is giving a "blanket okay for any type of ceiling tile to support the possible added weight of 3 cables of less than 1/2 in. in diameter on each ceiling tile. The proposal does not affirm that the ceiling tile industry was contacted of adding weight to lay on their product. This product is not part of the building structure, and is not designed to be suitable for supporting cables. I have seen ceiling tiles which look as if made of fiber glass insulation which has a finished surface on the exposed side of the ceiling. It is my belief that this ceiling tile would not accept additional weight upon it. I have contacted three ceiling tile companies or organizations on this proposal. They all suggested that their ceiling tiles are not to

support additional weight. I have provided copies of my e-mail contacts.

NOTE: Supporting Material is available at NFPA Headquarters.

PANEL ACTION: Reject.

PANEL STATEMENT: The recommendation of Comment 16-27a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications wires and cables in existing construction. The restrictions contained in Comment 16-27a limit both the number and size of wires and cables permitted on each ceiling panel, thereby controlling weight and accumulation so that cables can be easily moved aside to permit access. The submitter's concern about weight is addressed by decreasing the size of the cable to 1/4 inch and limiting the number of cables to three per each 10 ft x 10 ft area.

(Log #856)

16- 30 - (725-5): Accept in Principle in Part

SUBMITTER: Larry F. Miller, National Electrical Manufacturers Association (NEMA)

COMMENT ON PROPOSAL NO: 16-38

RECOMMENDATION: The Panel should continue to Accept the proposal but revise the Panel action text to read as follows:

725-5. Access to Electrical Equipment Behind Panels Designed to Allow Access.

Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use or maintenance. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.

b.1. Installation of cables in suspended lay-in type ceiling spaces shall comply with 300.11.

2. Installation of cables in other than suspended lay-in type ceiling spaces shall comply with 300.11 where the space is accessible.

3.Where the ceiling is not the lay-in type, and the space is not accessible, three cables less than 13 mm (0.5 in.) shall be permitted to be installed unsupported by the building structure between access points or access panels.

~~Buildings with existing cabling systems.~~

~~Where practicable, installation of cables shall comply with Section 300.11. Where impracticable to comply with Section 300.11, cables less than 13 mm (0.5 in) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.~~

~~1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.~~

~~2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum three supported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid."~~

SUBSTANTIATION: We agree with Mr. Egedsal's and Mr. Speer's negative comments that suspended ceilings are not intended to support electrical wires or cables.

Section 300-11(a)(1) (wiring located within the cavity of a fire-rated floor-ceiling or roof-ceiling) allows an exception for wiring that has been tested as part of the fire-rated assembly. This proposal could compromise the fire-rating of the ceiling by overriding that requirement. The words "or maintenance" have been added because so much of the damage occurs in ceiling spaces as various trades perform maintenance.

The submitter states that he has submitted companion proposals for Articles 725 760, 770, 820 and 830. If each of these articles will allow three cables per ceiling tile, this could result in a total of 18 cables per ceiling tile, which appears to be approaching the "excessive accumulation" the submitter agrees could be a hazard. Limiting the size and quantity of cable permitted to be fished in non-lay-in ceiling spaces will help control the weight of cable (combined with that permitted in the other articles referenced above) on these ceilings.

PANEL ACTION: Accept in Principle in Part.

The panel rejects the recommended addition of the word "maintenance."

The balance of the recommendation is accepted in principle.

PANEL STATEMENT: The term "normal building use" includes "maintenance." Refer to the recommendation and substantiation on Comment 16-27a.

16- 31 - (725-5): Accept in Principle

SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.

COMMENT ON PROPOSAL NO: 16-38

RECOMMENDATION: Revise as follows:

725-5. Access to Electrical Equipment Behind Panels Designed to Allow Access. Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.

b. Buildings with existing cabling systems. Where practicable, installation of cables shall comply with Section 300-11. Where impracticable to comply with Section 300-11, cables less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.

1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.

2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of ~~any one~~ each ceiling tile, i.e., up to three wires and cables are permitted to lay on a ceiling tile. The cables shall be run parallel to the ceiling grid.

SUBSTANTIATION: Proposed Section 725-5(b)(2), as presently written in Proposal 16-38, panel action, is confusing and could be interpreted as permitting a total of only three unsupported wires and cables above a suspended ceiling. The intent of the panel was that up to a maximum of three unsupported wires and cables may be routed across each and every ceiling tile. The revision proposed in this comment clarifies and accomplishes the intent of the panel. This is a companion comment and is intended to correlate with comments on Proposals 16-112, 16-159, 16-192, 16-276, and 16-332.

PANEL ACTION: Accept in Principle.

PANEL STATEMENT: Refer to the recommendation and substantiation on Comment 16-27a.

(Log #1163)

16- 32 - (725-5): Accept in Principle

SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.

COMMENT ON PROPOSAL NO: 16-38

RECOMMENDATION: Revise as follows:

725-5. Access to Electrical Equipment Behind Panels Designed to Allow Access. Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.

b. Buildings with existing cabling systems. ~~Where practicable, installation of cables shall comply with Section 300-11. Where impracticable to comply with Section 300-11,~~Cables less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.

1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.

2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.

Where the maximum number of cables permitted in 1 or 2 will be exceeded, installation of cables shall comply with Section 300.11.

SUBSTANTIATION: The Technical Correlating Committee has directed that Proposal 16-38 be revised to comply with the NEC Style Manual 3.2.1 relative to the use of unenforceable terms. The proposed revision contained in this comment removes the unenforceable terms "practicable" and "impracticable", the remaining text is in agreement with the NEC Style Manual 3.1.2 using the phrase "shall be permitted" to indicate allowed optional or alternate methods. The added text (final sentence) provides direction on how to proceed if the limits of 725-5(b)(1) or (2) will be exceeded. This is a companion comment and is intended to correlate with comments on Proposals 16-112, 16-159, 16-192, 16-276, and 16-332.

16- 33 - (725-5): Accept in Principle

SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.

COMMENT ON PROPOSAL NO: 16-38

RECOMMENDATION: Continue to accept in principle.

SUBSTANTIATION: Panel 16 should continue to accept this proposal in principle as it provides a reasonable and safe solution to placing a limited number of signaling and communications wires and cables in existing construction. The restrictions contained in the proposed change limit both the number and size of wires and cables permitted on each suspended ceiling panel. In this manner additional weight, as well as an accumulation of wires and cables that would otherwise restrict access above suspended ceiling panels, is controlled and limited. The limited number of cables permitted can easily be moved aside to permit access. Some concern has also been expressed that cables placed directly on the ceiling panels would degrade the fire rating of the ceiling. The suspended ceiling, part of a membrane that is intended to retard fire from spreading into the ceiling cavity, would be unaffected in its ability to retard the spread of fire by a limited number of wires and cables resting on top of the panels. This is a companion comment and is intended to correlate with comments on Proposals 16-112, 16-159, 16-192, 16-276, and 16-332.

PANEL ACTION: Accept in Principle.

PANEL STATEMENT: Refer to the recommendation and substantiation of Comment 16-27a. This action meets the intent of the submitter.

(Log #CC1602)

16- 27a - (725-5, 725-6, 725-7 and 525-9 (New)): Accept

Note: The Technical Correlating Committee directs that the references to Articles 640 and 650 be deleted because the panel did not accept similar requirements in those articles. The Technical Correlating Committee also directs that the FPN which contains a mandatory requirement be deleted to comply with the NEC Style Manual.

SUBMITTER: CMP 16

COMMENT ON PROPOSAL NO: 16-38

RECOMMENDATION: Renumber current Section 725-6 as 725-9.

Renumber current Section 725-7 as 725-6.

Retain the existing 1999 code text for Section 725-5 (unmodified).

Add new Section 725.7 to read as follows:

725.7 Installation of Circuits

Class 1, Class 2, and Class 3 circuits shall be installed in compliance with A or B.

A. New Ceiling Construction. The installation of cables in new ceiling construction shall comply with Section 300-11.

B. Existing Ceilings.

1. Fire-Rated Ceilings. The installation of cables in the cavity of an existing fire-rated ceiling assembly shall comply with Section 300-11.

2. Non-Fire-Rated Ceilings. For installations in the cavity of an existing non-fire-rated ceiling assembly, cables less than 6 mm (0.25 in) in diameter shall be permitted to be installed unsupported from the building structure in accordance with the following:

a. Fixed or Hard Ceilings. In areas having fixed or hard ceilings with access points or access panels, a combined total of three cables from Articles 640, 650, 725, 760, 770, 800, 820 and 830, shall be permitted to be placed between access points or access panels in the ceiling. Additional cables shall be installed in accordance with 300.11.

b. Suspended Lay-In Ceilings. In areas having suspended lay-in ceilings, in any 3 m by 3m (10 ft. x 10 ft) ceiling area, a combined total of three cables from Articles 640, 650, 725, 760, 770, 800, 820 and 830, shall be permitted to be installed directly on the ceiling grid. Additional cables shall be installed in accordance with 300.11.

FPN. Cables of all types are included in the total limit of three cables, not three cables from each article.

SUBSTANTIATION: Proposal 16-38 was accepted in principle to permit the installation of unsupported cables under limited conditions. The proposal text however, was too broad and unclear. The text of this comment clarifies the original intent. The new text includes requirements to comply with Section 300.11. Permitted installation conditions will not compromise the integrity of fire-rated ceilings. For non-fire-rated ceilings, the permitted relief from Section 300.11 is limited to very specific conditions. Section 725.5 is not being modified because the accessibility requirements should remain.

The sections have been renumbered so that they appear in a logical order.

PANEL ACTION: Accept.

NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 22

VOTE ON PANEL ACTION:

AFFIRMATIVE: 21

NEGATIVE: 1

EXPLANATION OF NEGATIVE:

SPEER: The panel's action on these comments greatly reduces the effectiveness of previous changes in the Code, which eliminated any unsupported cable laying on suspended ceilings, the panel's statement on Comment 16-29 indicates that the panel's action on Comment 16-27a provides a reasonable, safe, and practical solution to placing unsupported cables in areas having non-fire rated ceilings. I must respectfully disagree.

The permitted relief from Section 300.11 is limited to "very specific conditions." The conditions noted by the panel began as 3 cables, each less than 0.5 inch in diameter, on any one lay-in ceiling tile. The panel has now reduced that quantity of weight by limiting the accumulative load to 3 cables, each less than 0.25 inch in diameter, within any 10 ft. x 10 ft. area.

The panel's statement on Comment 16-29, further indicates that the restrictions contained in 16-27a, addressed the submitter's concern regarding added weight, by reducing both the size and number of allowable cables in any specific area. The question must be asked, by what process or method did the panel use to arrive at the "allowable" added weight? How was the determination made, that by reducing from 0.5 inch to 0.25 inch, the accumulated unsupported weight, added to the suspended ceiling system, would be satisfactorily reduced to meet the submitter's concerns?

The specific conditions of this "relief" from the requirements of Section 300.11 are not supported technically, or by any other form of substantiation. The panel adopted the original criteria of Proposal 16-38 and then modified those conditions under Comment 16-27a. In either example, there has never been any technical or other form of substantiation for the amount of added weight these changes will accumulate on the ceiling system.

By allowing any unsupported cable on the ceiling tile, we are adding extra weight to the suspended ceiling system, which may not have been designed to support that additional weight.

In conclusion, it is my opinion that the panel's substantiation of this action does not support these proposed changes to the Code. Further, there is no basis for the panel's assumption that the limits described in Comment 16-27a provide a safe solution to the perceived problem addressed by Proposal 16-38.

(Log #740)

16- 36 - (725-5(b)): Accept in Principle in Part
SUBMITTER: Richard P. Owen, City of St. Paul, Electrical Inspection
COMMENT ON PROPOSAL NO: 16-38
RECOMMENDATION: Replace (b) of the proposal with the following text:
(b) Buildings not Covered Under (a) Above. In areas having ceilings with access points or panels and having 900 mm (3 ft) or less vertical clearance above the ceiling, it shall be permissible to fish a maximum of 3 cables, each less than 13 mm (0.5 in.) in diameter, between access points in the ceiling.
SUBSTANTIATION: The Technical Correlating Committee directed Panel 3 Chair Raymond Weber to form a Task Group to review these proposals and to submit the results as comments to Panel 16. Task Group 3-16, consisting of Chair Weber, members Steven Speer; Lee Hewitt; Richard Owen and Ron Maassen held a conference call on October 3, 2000 and developed the above language as a comment. The Task Group was concerned with allowing unsupported cabling above suspended ceilings, since companion proposals for Articles 725, 760, 770, 800, 820 and 830 would also allow this limited cabling without support. The possible accumulation of cable allowed by all these articles would be excessive and would both limit access to a ceiling and conflict with Section 300.11. Rewording of (b) also eliminated the unenforceable terms "practicable" and "impracticable" as directed by the Technical Correlating Committee.
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: The panel rejects the specific limitations in the comment but accepts the principle of permitting a limited number of cables. The recommendation of Comment 16-27a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications wires and cables in existing construction.

(Log #976)

16- 37 - (725-5(b)(2)): Accept in Part
SUBMITTER: Palmer Hickman, Royersford, PA
COMMENT ON PROPOSAL NO: 16-38
RECOMMENDATION: Reject Proposal 16-38 and retain present 725-5 as it appears in the 1999 NEC.
SUBSTANTIATION: I would strongly urge Code-Making Panel 16 to reconsider their action on this proposal. The proposed 725.5(B)(2) would now permit three cables to be installed on the tile of a suspended ceiling, without providing any technical substantiation for this allowance.

I offer the following reasons against accepting this proposal.

1) Chapters 1-4 apply except as amended by Chapters 5, 6, and 7. Sections 300-11(a)(1) and (2) state wiring shall not be supported by ceiling assembly.

2) Section 725-5 deals with access to electrical equipment, not support of wiring

3) Code-Making Panel 3 reaffirmed their prohibition of ceiling assemblies being used beyond the manufacturers design parameters in the Panel Statement to Comments 3-53 and 3-57 of the 1998 ROC, and Proposal 3-68 of the 2001 ROP. In the later reference, Code-Making Panel 3 states: "The panel reaffirms its position that an independent means of support shall be provided for all wiring, not just branch circuit wiring...".

I understand that this proposed allowance of ceiling support only applies to buildings with existing cabling systems where it is "impracticable" to comply with 300-11. Impracticability does not provide technical substantiation to allow a ceiling assembly that has not been evaluated to support the potential additional load of three cables on each and every ceiling tile. Essentially, the ceiling assembly is expected to carry the additional load of potentially hundreds of cables installed directly on it. As an example, a 100 ft X 100 ft room with a suspended ceiling using 2 ft x 2 ft tiles, would be expected to carry the full weight of 150 cables.

The substantiation offered by the submitter of this proposal does not even support the proposed change. He claims that "a limited amount of wiring or cabling laid directly on a suspended ceiling is permitted..." without stating where this permission is given, and by whom. The entire substantiation of the submitter seems contrary to the action of the panel. He begins his substantiation by stating "Section 725-5 may be misinterpreted to mean that conductors and cables may not be placed directly on suspended ceiling." He notes that the 1999 NEC Handbook "Figures 725-2 and 725-3 lead the reader to conclude that no wires or cables are permitted to rest directly on the suspended ceiling." The submitter also stated Code-Making Panel 16 responded to a proposal to Article 725 (1992 TCD Comment 16-18) that the proposed requirement "...would still allow some cabling of a limited quantity above the ceiling tile, but not an excessive amount." Note the words "above the ceiling tile", not on the ceiling tile. I feel these examples are not misinterpretations, but rather correct interpretations, and substantiation to reject this proposal.

In conclusion, I respectfully disagree with the Panel Action on this Proposal. I feel the implications are quite serious. I find no technical substantiation to warrant such a dramatic change. The substantiation of the submitter does not appear to support this change, but rather the rejection of it.
PANEL ACTION: Accept in Part.
The panel accepts the portion of the comment to retain Section 725.5, and rejects the portion of the comment to reject Proposal 16-38.
PANEL STATEMENT: Refer to the recommendation and substantiation on Comment Log 16-27a. Also refer to the panel action and statement on Comment 16-29.

(Log #1254)

16- 38 - (725-5(b)(2)): Reject
SUBMITTER: J. Paul Spinn, USG Research & Technology Center
COMMENT ON PROPOSAL NO: 16-38
RECOMMENDATION: Delete the following text:
In areas having suspended lay in ceiling, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.
SUBSTANTIATION: By allowing a maximum of three unsupported cables on top of any one (or more) ceiling tiles, the fire-rating of the assembly and the Class A surface burning characteristic requirement, which includes flame spread and smoke development, could be jeopardized. By decreasing the fire-rating of the plenum assembly and the surface burning characteristic of the ceiling tile, the life safety of the occupants can be negatively affected. By rejecting this proposal, these problems can be eliminated.
To substantiate the comment made for the proposal, four key points are provided:
[1] For a fire rated floor/ceiling or roof/ceiling assembly, placement of unsupported cables on top of any one ceiling tile or a row of ceiling tiles could invalidate the fire-rating for a particular assembly. The rationale for this argument are:
(a) The weight of the cables could cause premature tile fallout leading to an early failure of the assembly, which is tested in accordance with NFPA 251 or ASTM E 119.
(b) The increased heat of combustion associated with the cable jackets, which commonly use plastics, will add to the total fire load of an assembly. As the total fire load increases for an assembly, the fire endurance of the assembly will decrease, which could jeopardize an assembly's fire-rating.
[2] For a Class A ceiling, placement of unsupported cables on the ceiling can effect flame spread and smoke development performance and jeopardize the required Class A rating for the ceiling tiles. The rationale for this argument are:
(a) The flame spread will increase due to the increased total heat load, which is caused by the plastic on the cable jacket.
(b) The smoke development will increase due to the cable jackets, which are usually plastic such as PVC or CPVC.
[3] The placement of unsupported cables on top of any one or more ceiling tiles presents potential life safety issues for occupants due to the decreased fire-rating of the floor/ceiling or roof/ceiling or an increase in the ceiling surface burning characteristics.
[4] Placement of unsupported cables on top of any one ceiling tile or a row of ceiling tiles would increase ceiling tile sag due to increased weight of the cables on the ceiling tiles, and would impair the accessibility of the ceiling plenum.
PANEL ACTION: Reject.
PANEL STATEMENT: The recommendation of Comment 16-27a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications wires and cables in existing construction. The restrictions contained in Comment 16-27a limit both the number and size of wires and cables permitted on each ceiling panel, thereby controlling weight and accumulation so that cables can be easily moved aside to permit access. The submitter's concern about weight is addressed by decreasing the size of the cable to 1/4 inch and limiting the number of cables to three per each 10 ft x 10 ft area. The revised text precludes the installation of cables in all fire-rated ceiling assemblies.

(Log #2083)

16- 39 - (725-5(b)(2)): Accept in Principle in Part
SUBMITTER: Marcelo M. Hirschler, GBH International
COMMENT ON PROPOSAL NO: 16-38
RECOMMENDATION: Revise text as follows:
725-5. Access to Electrical Equipment Behind Panels Designed to Allow Access
Access to equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).
a. New building construction (e.g. renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.
b. Buildings with existing cable systems. Where practicable, installation of cables shall comply with Section 300.11. Where impracticable to comply with Section 300.11, in those areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables less than 13 mm (0.5 in) in diameter, between access points in the ceiling. ~~cables less than 13 mm (0.5 in) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.~~
~~1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.~~
~~2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.~~
SUBSTANTIATION: The permission granted by the panel to install cables on suspended ceiling tiles should be rescinded. Neither cables nor any other item should be installed on top of a suspended ceiling tile. The support systems of suspended ceilings are not designed to resist any significant amount of weight without being deflected or broken.
This issue has been raised on Proposal 16-192 (log 1665) in negative comments by two panel members, Mr Egesdal and Mr Speer, who both correctly point out that suspended ceiling tiles are not intended to support the weight of electrical cables. Mr. Sandy Egesdal repeats his negative comment on this proposal.
The point made by the Technical Correlating Committee that such use would constitute an exposed use of cables is an additional consideration to rejecting this part of the proposal.
PANEL ACTION: Accept in Principle in Part.
The panel accepts the principle of permitting a limited number of cables to be installed in a fixed or hard ceiling. The panel rejects the balance of the submitter's recommendation including the limiting of the installation of cables in a suspended lay-in ceiling.
PANEL STATEMENT: The recommendation of Comment 16-27a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications wires and cables in existing construction.

16- 40 - (725-7): Accept
SUBMITTER: Larry F. Miller, National Electrical Manufacturers Association (NEMA)
COMMENT ON PROPOSAL NO: 16-39
RECOMMENDATION: The Panel should continue to Accept the proposal in Principal but revise the Panel recommendation as follows:
Mechanical Execution of Work. Communications circuits and equipment shall be installed in a neat and workmanlike manner. Cables installed exposed on the outer surface of ceiling and sidewalls shall be supported by the structural components of the building structure...".
SUBSTANTIATION: To clarify this cable is in the room, not in the ceiling void space.
PANEL ACTION: Accept.
PANEL STATEMENT: The panel notes that the only effect of this action is to add the word "outer." The remaining text is not affected.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 22
VOTE ON PANEL ACTION:
AFFIRMATIVE: 22

(Log #1155)

16- 41 - (725-7): Reject
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-39
RECOMMENDATION: Delete 725-7 and incorporate the information in 725-5 as follows:
725-5. ~~Access to Electrical Equipment Behind Panels Designed to Allow Access~~ Mechanical Execution of Work, Class 1, Class 2, and Class 3 circuits shall be installed in a neat and workmanlike

manner. Access to electrical equipment shall not be denied by an accumulation of ~~wires and~~ cables and conductors that prevents removal of panels. Cables and conductors shall be installed in such a manner that ~~the cable~~ they will not be damaged by normal building use. ~~Access to electrical equipment behind ceilings designed to allow access~~ Cables and conductors installed exposed shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables and conductors shall comply with Section 300-11. Cables and conductors shall be supported by structural components of the building. Such cables and conductors shall be attached to structural components at intervals not exceeding 1.52 m (5 ft) and within 305 mm (12 in.) from every cabinet, box, or fitting by straps, staples, hangers or similar fittings designed and installed so as not to damage the cable or conductors. The installation shall also conform with Section 300-4(d).

b. Buildings with existing cable systems. Where practicable, installation of cables and conductors shall comply with ~~Section 300-11~~ 725-5(a), . Where impracticable to comply with ~~Section 300-11~~ 725-5(a), cables and conductors less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.

1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.

2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of hree unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.

SUBSTANTIATION: Sections 725-5 and 725-7 actually address the same issue, the mechanical execution of work. Accessibility behind panels designed to allow access is really an "execution of work" issue. Additionally, the Technical Correlating Committee has identified a potential conflict between proposed revised 725-5 and 725-7. This comment editorially combines 725-5 and 725-7 into a single Section 725-5 requiring attachment to the building structure of exposed cables and conductors and, where impracticable to do so, permits a limited number of cables and conductors of specified maximum size to be placed on suspended ceiling tiles. It accommodates the intent of both proposals that cables and conductors should be supported by the building structure, but in extenuating circumstances in existing construction, a limited number and weight of cables and conductors may be placed on a suspended ceiling. This is a companion comment to similar comments to Proposal 16-115, 16-159a, 16-192a, 16-276a, and 16-333a.
PANEL ACTION: Reject.
PANEL STATEMENT: The sections should not be combined. Refer to the recommendation and substantiation for Comment 16-27a where these recommendations are addressed.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 22
VOTE ON PANEL ACTION:
AFFIRMATIVE: 22

(Log #1425)

16- 42 - (725-7): Accept in Part
SUBMITTER: Kari Barrett, American Chemistry Council
COMMENT ON PROPOSAL NO: 16-39
RECOMMENDATION: Delete the following text:
~~Such cables shall be attached to structural components at intervals not exceeding 1.52 m (5 ft) and within 305 mm (12 In.) from every cabinet, box or fitting by straps, staples, hangers or similar fittings designed and installed so as not to damage the cable. The installation shall also conform with Section 300-4(d).~~
SUBSTANTIATION: The addition of this text would make the mandatory requirements of this section overly specific. The present wording is sufficient guidance to both the installer and the authority having jurisdiction.
PANEL ACTION: Accept in Part.
Revise the third sentence of the panel action text of Proposal 16-39 to read as follows:
"Such cables shall be attached to structural components by straps, staples, hangers or similar fittings designed and installed so as not to damage the cable."
PANEL STATEMENT: The panel accepts the removal of specific distances for the attachment of the cable. The panel does not agree that the existing code wording is sufficient guidance to both the installer and the authority having jurisdiction.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 22
VOTE ON PANEL ACTION:
AFFIRMATIVE: 21
NEGATIVE: 1
EXPLANATION OF NEGATIVE:
SPEER: The inclusion of specific distances for spacing attachment points if not "overly specific" in its guidance offered to installers or the authority having jurisdiction. The specific distances mentioned, merely ensure that cables installed will be properly supported and, thus, protected from damage.

(Log #1640)

16- 43 - (725-7): Reject
SUBMITTER: Andy Scott, National Cable Television Association
COMMENT ON PROPOSAL NO: 16-39
RECOMMENDATION: Reject Proposal 16-39.
SUBSTANTIATION: NCTA, on behalf of the cable television industry, strongly urges Panel 16 to reject these proposals. While attachment every 5 ft may be a practice in many cases, it also may be overly restrictive and unnecessary in others. The requirement to support cables every 5 ft is outside the scope of the code. The NCTA urges Panel 16 not to allow the NEC to serve as an Installation Manual.
PANEL ACTION: Reject.
PANEL STATEMENT: The panel action on Comment 16-42 addresses the concerns in the submitter's substantiation.

(Log #1912)

16- 48 - (725-21): Accept
SUBMITTER: Michael I. Callanan, International Brotherhood of Electrical Workers
COMMENT ON PROPOSAL NO: 16-43
RECOMMENDATION: Reject this proposal.
SUBSTANTIATION: The submitter of this proposal makes no claim that Class 1 Power-limited Circuits are unsafe or present any type of hazard. His only reason for recommending that these types of circuits be deleted is that they are not needed because no one uses them. For evidence, he claims that there are no listed products that meet the requirements of Section 725-21(a). This is not true.

The only requirement for a Class 1 power limited circuit in Section 725-21(a) is that they be supplied from a source that has a rated output of not more than 30 volts and 1000 volt-amperes. Unlike the requirements in Section 725-4(a) for Class 2 and 3 power sources, which are required to be listed as either Class 2 or Class 3, there is no such requirement for Class 1 power-sources. As a result, UL does not list them as Class 1 and would respond to any inquiry by saying that they have no Class 1 products listed. However, they do have listed products that meet the requirements for Class 1 products.

The decision whether to install these products as Class 1 power sources is not made by the manufacturer; it is made by the installer. Deleting Class 1 power-limited circuits from the Code will unnecessarily deny the user of this code the option of taking advantage of the benefits provided by using Class 1 wiring methods.

This comment represents the official position of the International Brotherhood of Electrical Workers Codes & Standards Committee.

16- 55 - (725-26): Reject
SUBMITTER: Kenneth P. White, Olin Corp.
COMMENT ON PROPOSAL NO: 16-51a
RECOMMENDATION: The panel should have rejected the proposal.
SUBSTANTIATION: This proposal is meant for conductors not cables and with tray cable and the outer jacket of the cable provides for sufficient insulating protection. The submitter has not shown that a significant problem exists.
PANEL ACTION: Reject.
PANEL STATEMENT: Refer to the panel actions and statements on Comments 16-57 and 16-60. Refer to the definition of conductor in Article 100.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 22
VOTE ON PANEL ACTION:
AFFIRMATIVE: 20
NEGATIVE: 2
EXPLANATION OF NEGATIVE:
HUGHES: See my explanation of negative vote on Comment 16-57.
RAO: For over twenty years this panel has maintained its position that it does not intend for insulation to be the only means of separation of power conductors and control conductors even though insulation materials and characteristics have improved tremendously over these years.
Where 600V insulation is used on power conductors, the insulation is the only separation from metal parts or ground. In fact, between power conductors the separation value is doubled to 1200 volts. This also would apply to the additive rating between power and control conductors.
Power and control conductors eventually come together somewhere in the system where the only separation is insulation.
Allowing power and control conductors to be run in cable trays would be a step forward in correcting an unnecessary restriction.

(Log #2207)

16- 56 - (725-26): Reject
SUBMITTER: Joyce Evans Blom, The Dow Chemical Company
COMMENT ON PROPOSAL NO: 16-51a
RECOMMENDATION: Revise (b)(4) from the panel proposal as follows:
(4) In cable trays, where all conductors are insulated for the maximum voltage of any one conductor installed in the cable tray, or where the Class 1 circuit conductors and power-supply conductors not functionally associated with them are separated by a solid fixed barrier of material compatible with the cable tray, or where the power-supply or Class 1 circuit conductors are in a metal-enclosed cable.
SUBSTANTIATION: Current industry practice in 600 volt class industrial cable tray installations is to route motor power and control (Class 1) conductors for several different motors in the same tray. Typically, these cables in the tray would include power-only, control-only or combined power and control. The motors are generally not directly associated with one another. There has been no safety problem with this type of installation as long as the conductors are rated for cable tray service and all the cables have the same insulation level.
The NEC should support the present industry practice because this is a very common type of installation and there has not been a safety problem - provided all conductors are insulated for 600 volts and rated for tray cable service. My suggested alternate wording is shown above.
PANEL ACTION: Reject.
PANEL STATEMENT: The comment would permit intermixing of power, Class 1, Class 2 and Class 3 circuits with only the conductor or cable insulation used for separation between circuits. The panel does not intend for insulation to be the only means for separation.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 22
VOTE ON PANEL ACTION:
AFFIRMATIVE: 20
NEGATIVE: 2
EXPLANATION OF NEGATIVE:
RAO: See my explanation of negative vote on Comment 16-55.
HUGHES: This comment should have been accepted. The panel statement substantiating its rejection of this comment is flawed. It states this comment would permit intermixing power, Class 1, Class 2, and Class 3 circuits with only the insulation as separation. This section of Article 725 (Part B, 725-21 through 725-29) addresses Class 1 circuits only and does not in any way address Class 2 and Class 3 circuits.

(Log #828)

COMMENT ON PROPOSAL NO: 16-51a
RECOMMENDATION: Delete the reference to cable trays.
SUBSTANTIATION: • Neither the Panel Statement nor the underlying originating Proposal (16-54) offers a substantive safety issue that this broad reference to cable trays rectifies for public review. That is because there is no general safety issue that it rectifies.
• Class 1 circuits essentially use Chapter 3 wiring methods. Where wiring methods requiring functional conductor/circuit separation is a safety issue, it is properly addressed in Section 725-8 and Articles 700 and 701.
PANEL ACTION: Reject.
PANEL STATEMENT: Proposal 16-51a provides for separation of circuits in cable trays in a manner consistent with other wiring methods in Article 725 and provides restrictions beyond those provided in Chapter 3.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 22
VOTE ON PANEL ACTION:
AFFIRMATIVE: 20
NEGATIVE: 2
EXPLANATION OF NEGATIVE:
HUGHES: This comment should have been accepted. This comment and the originating proposal address separation of Class

1 circuits and power supply circuits only. Any needed restrictions for separation of Class 1 circuits from Class 2 or Class 3 circuits do not apply here. Using cable/conductor insulation as the means of physical separation per 300-3(c)(1) is appropriate and no further modification of that general rule should be included in Article 725.
RAO: See my explanation of negative vote on Comment 16-55.

(Log #829)

16- 58 - (725-26(b)): Reject
SUBMITTER: Robert B. Alexander, Fluor Daniel
COMMENT ON PROPOSAL NO: 16-54
RECOMMENDATION: Reject the proposal.
SUBSTANTIATION: • Neither the Panel Statement nor the Proposal offers for public review a substantive safety issue that this proposal corrects.
• Class 1 circuits essentially use Chapter 3 wiring methods. Where wiring methods requiring functional conductor/circuit separation is a genuine safety issue, it is properly addressed in Section 725-8 and Articles 700 and 701.
• This proposal creates unnecessary general costs to Class 1 wiring methods with no general safety benefits that are identifiable and necessary.
• Even if the system were to perform better, which is unlikely, it is inappropriate to make it a requirement unless it also corrects a known safety issue - not a speculated one.
NFPA 70 90-1 Purpose
(a) Practical Safeguarding. The purpose of this Code is the practical safeguarding of persons and property from hazards arising from the use of electricity.
(b) Adequacy. This Code contains provisions that are considered necessary for safety. Compliance therewith and proper maintenance will result in an installation that is essentially free from hazard but not necessarily efficient, convenient, or adequate for good service or future expansion of electrical use.
PANEL ACTION: Reject.
PANEL STATEMENT: Refer to panel actions and statements on Comments 16-57 and 16-60.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 22

(Log #1459)

16- 59 - (725-26(b)): Reject
SUBMITTER: Peter D. Noval, Jr., Philadelphia, PA
COMMENT ON PROPOSAL NO: 16-51a
RECOMMENDATION: Revise text to read as follows:
"(B) Class 1 Circuits with Power Supply Circuits. Class 1 circuits shall be permitted to be installed with power supply conductors as specified in (1) through 3. (Delete reference to (4).)
(1) In a Cable, Cable Tray, Enclosure, or Raceway. Class 1 circuits and power supply circuits shall be permitted to occupy the same cable, cable tray, enclosure or raceway only where the equipment powered is functionally associated.
Exception: In cable trays, Class 1 circuit conductors and power supply conductors not functionally associated with them shall be permitted where one of the following conditions is met:
(a) The Class 1 circuit conductors and power supply conductors are separated by a solid fixed barrier of a material compatible with the cable tray.
(b) The power supply or Class 1 circuit conductors are in a metal-enclosed case.
(2) In Factory-or Field-Assembled Control Centers. Class 1 circuits and power supply circuits shall be permitted to be installed in factory-or field-assembled control centers.
(3) In a Manhole. Class 1 circuits and power supply circuits shall be permitted to be installed as underground conductors in a manhole in accordance with one of the following:
(a) The power supply or Class 1 circuit conductors are in a metal-enclosed cable or Type VF cable.
(b) The conductors are permanently separated from the power supply conductors by a continuous firmly fixed non-conductor, such as flexible tubing, in addition to the insulation on the wire.
(c) The conductors are permanently and effectively separated from the power supply conductors and securely fastened to racks, insulators, or other approved supports."
Delete the following:
~~(4) In cable trays, where the Class 1 circuit conductors and power supply conductors not functionally associated with them are separated by a solid fixed barrier of a material compatible with the cable tray, or where the power supply or Class 1 circuit conductors are in a metal-enclosed cable.~~
SUBSTANTIATION: Utilization of cable tray for functionally associated Class 1 Circuits and Power Supply Circuits is only implied by this section as presently proposed by ROP #16-51a. Revision to text (by comment) clarifies that Class 1 Circuits and Power Supply Circuits are permitted to occupy the same cable tray where equipment powered is functionally associated. It also provides a clear exception to this statement for non-functionally associated wiring in cable trays. The revised text should prove easier to interpret and enforce, helping designers, installers and inspectors alike.
PANEL ACTION: Reject.
PANEL STATEMENT: The text as recommended in Proposal 16-51a is clear and provides for the use of cable tray. In addition the proposed revision does not comply with the Manual of Style as specified in Section 3.1.4.

16- 60 - (725-26(b)(4)): Reject
SUBMITTER: Kari Barrett, American Chemistry Council
COMMENT ON PROPOSAL NO: 16-51a
RECOMMENDATION: Revise text as follows:
725-26(b)(4) - In cable trays. Class I circuits and power supply circuits shall be permitted to be installed in cable tray.
SUBSTANTIATION: Installing motor leads and motor control wiring (both functionally associated and not functionally associated) in the same cable tray using type TC cable has long been an accepted method of wiring in industry. It has proven to be a reliable and cost effective method. The motor control wiring is sometimes Class I wiring. Incorporating the proposed wording in 725-26(b)(4) would require extraordinary and unnecessary installation methods to ensure separation when the lack of separation has never presented a problem. The Panel proposal already allows mixing these cables in Motor Control Centers per 725-26(b)(2). Revising the wording per my comment will accomplish two things. It will continue to permit a safe, reliable, and cost effective installation method and will also recognize cable tray as a wiring method.
PANEL ACTION: Reject.
PANEL STATEMENT: The intent of the panel is to require that in cable trays 1.) physical separation other than insulation, or 2.) that the power supply circuits be functionally associated with the Class 1 circuits.

(Log #1458)

16- 61 - (725-26(b)(4)): Reject
SUBMITTER: Paul E. Guidry, Fluor Daniel, Inc.
COMMENT ON PROPOSAL NO: 16-51a
RECOMMENDATION: This proposal should be rejected.
SUBSTANTIATION: There isn't any logical reason why Class 1 Circuits should be separated from lighting and power circuits, all wiring is rated 600V insulation. In this proposal, the proposed Section 725.26(b)(1) requires a barrier to be placed in a tray to separate Class 1 Circuits from power conductors not functionally associated with them. This isn't necessary. No documented safety hazards were presented in the proposal to warrant this rule. This requirement would place undue hardship on industrial installations.

PANEL ACTION: Reject.
PANEL STATEMENT: Refer to the panel action and statement on Comments 16-57 and 16-60.

(Log #1525)

16- 62 - (725-26(b)(4)): Reject
SUBMITTER: Carl J. Fredericks, S. Houston, TX
COMMENT ON PROPOSAL NO: 16-51a
RECOMMENDATION: Revise (b)(4) from the panel proposal as follows:
(4) In cable trays, where all conductors are insulated for the maximum voltage of any conductor in the cable tray, or where the Class I circuit conductors and power-supply conductors not functionally associated with them are separated by a solid fixed barrier of a material compatible with the cable tray, or where the power-supply or Class 1 circuit conductors are in a metal-enclosed cable.
SUBSTANTIATION: It is very common for 600 volt class industrial cable tray installations to include motor power and control (Class 1) conductors for several different motors in the same tray. The cables in the tray may be power-only, control-only, or combined power and control (usually they are a mix of all three), and the motors are generally not directly functionally associated with one another.
This is a very common type of installation and there is no safety problem with it, as long as all conductors are insulated for 600 volts and rated for tray cable service, and the NEC should not disallow it. One way to do so is with the suggested change as given above.
PANEL ACTION: Reject.
PANEL STATEMENT: Refer to the panel action and statement on Comment 16-60.

16- 64 - (725-27(c)): Accept in Part
SUBMITTER: Craig M. Wellman, Newark, DE
COMMENT ON PROPOSAL NO: 16-57
RECOMMENDATION: Please continue to reject this proposal and leave Article 727 as an independent article. In the next code cycle, Article 725 should be split into two or more articles and harmonization with IEC low voltage systems should be considered for adoption.
SUBSTANTIATION: Article 727 was created because it was impossible to modify Article 725 to allow industrial users to meet code requirements. Article 727 is clearly understood and applied by its users in a way that assures safety and code compliance. By having a separate article for its applications much confusion has been eliminated.
Let's keep moving toward a more useable code vs going back to the bad old days. Future usability efforts should focus on improving ease of application of Article 725 as it exists today. That can most readily be accomplished by splitting it into two articles. Another article may be appropriate to enable harmonization with IEC low voltage systems. Providing separate articles for each type of application and its wiring systems greatly improves understanding and reduces code violations
PANEL ACTION: Accept in Part.
PANEL STATEMENT: The panel accepts the recommendation to leave Article 727 as an independent article. The panel rejects that Article 725 should be split.

16- 65 - (725-27(c)): Accept in Part
SUBMITTER: John E. Propst, Equilon Enterprises, LLC
COMMENT ON PROPOSAL NO: 16-56
RECOMMENDATION: The purpose of this comment is to support the action of the panel and to reject the suggestion of the Correlating Committee to reconsider incorporating Article 727 into Article 725.
SUBSTANTIATION: In addition to the substantiation provided by the panel in rejecting this proposal, the clarity of Article 727 should not be compromised by trying to integrate it into the already very confusing Article 725. One of the primary reasons for the creation of Article 727 by CMP 7 was to provide a clear and well defined wiring method that industry could successfully apply to industrial process control because of the existing confusion and misapplication of PLTC cables for industrial controls. In general, ITC wiring is meeting the needs of industry. Trying to integrate Article 727 into 725 will only result in unnecessary confusion and a compromise in safety.
PANEL ACTION: Accept in Part.
PANEL STATEMENT: The panel accepts the comment regarding the support of the panel action. The panel rejects the recommendation to reject reconsideration of the Technical Correlating Committee suggestion.

16- 66 - (725-27(c)): Reject
SUBMITTER: Kari Barrett, American Chemistry Council
COMMENT ON PROPOSAL NO: 16-56
RECOMMENDATION: Delete entire proposal 16-56 (new section 725-27(c).
SUBSTANTIATION: One of the most confusing and hard to interpret Articles in the NEC is Article 725. When Article 727 was introduced to the NEC in 1996, it permitted an alternate wiring method for circuits that do not exceed 5 amperes and 150 volts. It is particularly suited for instrumentation circuits in industrial establishments where qualified persons perform service and maintenance. Application of Article 727 is very clear and the requirements are easy to understand and interpret. Incorporating Article 727 into Article 725 will only add to the complexity and confusion of an already complex and confusing Article 725.
PANEL ACTION: Reject.
PANEL STATEMENT: The panel cannot "delete" a proposal. The panel has rejected Proposal 16-56 through actions on Comments 16-67 and 16-68.

16- 69 - (725-42 and 725-10): Reject
SUBMITTER: Kari Barrett, American Chemistry Council
COMMENT ON PROPOSAL NO: 16-62a
RECOMMENDATION: Delete new Section 725-42 and Section 725-10.
SUBSTANTIATION: The need for new Section 725-42 and Section 725-10 is unsupported. There is not adequate substantiation to require Class 2 wiring to be identified when using a higher class wiring method.
PANEL ACTION: Reject.
PANEL STATEMENT: The marking is required. The panel reaffirms its initial action as supported by the substantiation of Proposal 16-62a.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 22
VOTE ON PANEL ACTION:
AFFIRMATIVE: 21
NEGATIVE: 1
EXPLANATION OF NEGATIVE:
HUGHES: This comment should have been accepted. Identification of Article 725 circuits per their class at all equipment, terminal locations, and junction locations, is a solution to a nonexistent problem. This requirement will add unnecessary cost and will not result in any meaningful practical safeguarding of persons and property from hazards arising from the use of electricity.

(Log #415)

16- 70 - (725-52, 725-42, 725-10): Reject
SUBMITTER: Dan Leaf, Palmdale, CA
COMMENT ON PROPOSAL NO: 16-62a
RECOMMENDATION: Reject proposal.
SUBSTANTIATION: Permission to install Class 2 or 3 circuits using Class 1 wiring methods is unnecessary since it is not presently prohibited. Section 90-3 states Chapters 1, 2, 3, and 4 apply generally except as amended by this chapter. The FPN for 725-1 indicates alternative requirements are given with regard to... and wiring methods. An alternative to Chapter 3 wiring methods is an option, not a requirement.

The Department of Public Works of the City of Los Angeles has for many years specified that all wiring in public buildings be in raceways.

Sections 725-54(a)(1) and Exceptions No. 4(a)(2), (a)(3), Exception No. 1(b)(1)(2)(3)(5), 725-61(b) ex., (e) Exception No. 1 ex., indicate raceway and cable wiring methods.

If these Class 2 and 3 circuits become defacto Class 1 circuits, 725-28 appears to negate the need for proposed Exception No. 1, which doesn't limit the exception to only the reclassified conductors.

Proposed (b) is already in the Code.

I agree with Mr. Hughes' comment re: Proposed 725-10.
PANEL ACTION: Reject.
PANEL STATEMENT: The reason for the change is to provide requirements to describe how to install Class 2 and Class 3 circuits using Class 1 wiring methods. The panel wants to make it clear that wiring methods such as the use of raceway or other Chapter 3 wiring methods are acceptable for Class 2 and 3 circuits as long as they are identified.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 22
VOTE ON PANEL ACTION:

HUGHES: See my explanation of negative vote on Comment 16-69.

(Log #CC1601)

16- 70a - (725-52(a)): Accept
Note: It was the action of the Technical Correlating Committee that the Fine Print Note to 725-52(A) in Proposal 16-62a be removed and a new second sentence be added to 725-52(A), Exception No. 2 of the Recommendation in this Comment to state: "Class 2 and Class 3 circuits reclassified and installed as Class 1 circuits shall not be classified as Class 2 or Class 3 circuits, regardless of the continued connection to a Class 2 or Class 3 power source." This action corrects the violation of the NEC Style Manual prohibiting mandadory language in Fine Print Notes.
SUBMITTER: CMP 16
COMMENT ON PROPOSAL NO: 16-62a
RECOMMENDATION: Renumber Exception No. 3 of the recommendation of Proposal 16-62 as Exception No. 2 and insert into Section 725-52(a) of the committee action of Proposal 16-62a, positioning it between Exception No. 1 and the Fine Print Note (FPN).
Exception No. 2 will read as follows:
Exception No. 2: Class 2 and Class 3 circuits shall be permitted to be reclassified and installed as Class 1 circuits if the Class 2 and Class 3 markings required in Section 725-42 are eliminated and the entire circuit is installed using the wiring methods and materials in accordance with Part B, Class 1 circuits.
SUBSTANTIATION: Panel Proposal 16-62a is a rewrite of Proposal 16-62. The panel made two changes to Proposal 16-62:
1. Deleted Section 725-52(a) Exception No. 2 to correlate with the action to reject Proposal 16-58.
2. Added new Section 725-10 regarding identification of circuits.

Section 725-52(a) Exception No. 3 in Proposal 16-62 was inadvertently omitted from Panel Proposal 16-62a.

The panel statement for Panel Proposal 16-62a addresses the use of Class 2 and Class 3 circuits installed as Class 1 circuits. The panel statement also addresses the need for identification of circuits in the new Section 725-10.

The panel statement does not include substantiation for the deletion of Exception No. 3 in Proposal 16-62 therefore it is apparent that the exception was omitted from Proposal 16-62a. Notes from a CMP-16 member indicates that this Exception should have been included in Proposal 16-62a.

Additionally, if both Exception No. 2 and No. 3 had been deleted in Proposal 16-62a, Exception No. 1 would have been changed to just Exception. This further suggests that the original Exception No. 3 should have been retained as Exception No. 2.
PANEL ACTION: Accept.

16- 72 - (725-54 and 760-55): Accept in Principle
SUBMITTER: Stanley D. Kahn, Tri-City Electric Co., Inc.
COMMENT ON PROPOSAL NO: 16-64
RECOMMENDATION: Reconsider the proposal but revise the wording and substitute the wording in parallel Section 760-55 to read as follows:
725.54. Installation of Conductors and Equipment In Cables, Compartments, Cable Trays, Enclosures, Manholes, Outlet Boxes, Device Boxes and Raceways for Class 2 and Class 3 Circuits. Conductors and equipment for Class 2 and Class 3 circuits shall be installed in accordance with Sections 725.55 through 725.58.
725.55. Separation from Electric Light, Power, Class 1, Non-Power-Limited Fire Alarm Circuit Conductors, and Medium Power Network-Powered Broadband Communications Cables.
725.55.1. Cables and conductors of Class 2 and Class 3 circuits shall not be placed in any cable, cable tray, compartment, enclosure, manhole, outlet box, device box, raceway, or similar fitting with conductors of electric light, power, Class 1, non-power-limited fire alarm circuits, and medium power network-powered broadband communications circuits unless permitted by 725.55.2 through 725.55.10 below.
725.55.2. Class 2 and Class 3 circuits shall be permitted to be installed together with Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits when they are separated by a barrier.
725.55.3. In enclosures, Class 2 and Class 3 circuits shall be permitted to be installed in a raceway to separate them from Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits.
725.55.4. Class 2 and Class 3 circuit conductors in compartments, enclosures, device boxes, outlet boxes, or similar fittings shall be permitted to be installed with Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits where they are introduced solely to connect the equipment connected to Class 2 and Class 3 circuits, and
725.55.4.1. The electric light, power, Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuit conductors are routed to maintain a minimum of 6 mm (0.25 in) separation form the conductors or cables of Class 2 and Class 3 circuits, or
725.55.4.2. The circuit conductors operate at 150 volts or less to ground and also comply with one of the following:

(a) The Class 2 and Class 3 circuits are installed using Type CL3, CL3R, or CL3P or permitted substitute cables, provided these Class 3 cable conductors extending beyond the jacket are separated by a minimum of 6 mm (0.25 in) or by a nonconductive sleeve or nonconductive barrier from all other conductors, or

(b) The Class 2 and Class 3 circuit conductors are installed as a Class 1 circuit in accordance with Section 725.21.

725.55.5. Class 2 and Class 3 circuit conductors entering compartments, enclosures, device boxes, outlet boxes, or similar fittings shall be permitted to be installed with Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits where they are introduced solely to connect the equipment connected to Class 2 and Class 3 circuits and if they must enter an enclosure that is provided with a single opening, they shall be permitted to enter through a single fitting (such as a tee) provided the conductors are separated from the conductors of the other circuits by a continuous and firmly fixed nonconductor, such as flexible tubing.
725.55.6. Underground Class 2 and Class 3 circuit conductors in a manhole shall be permitted to be installed with Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits where one of the following conditions is met.
725.55.6.1. The electric light, power, Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuit conductors are in a metal-enclosed cable or Type UF cable.
725.55.6.2. The Class 2 and Class 3 circuit conductors are permanently and effectively separated from the conductors of other circuits by a continuous and firmly fixed nonconductor, such as flexible tubing, in addition to the insulation or covering on the wire.
725.55.6.3. The Class 2 and Class 3 circuit conductors are permanently and effectively separated from conductors of the other circuits and securely fastened to racks, insulators, or other approved supports.
725.55.7. Class 2 and Class 3 conductors as permitted by Section 780-6(a) shall be permitted to be installed in accordance with Article 780.
725.55.8. Class 2 and Class 3 circuit conductors shall be permitted to be installed in cable trays, where the conductors of the electric light, Class 1 and non-power-limited fire alarm circuits are separated by a solid fixed barrier of a material compatible with the cable tray or where the Class 2 or Class 3 circuits are installed in Type MC cable.
725.55.9. In hoistways, Class 2 or Class 3 circuit conductors shall be installed in rigid metal conduit, rigid nonmetallic conduit, intermediate metal conduit or electrical metallic tubing. For elevators or similar equipment, these conductors shall be permitted to be installed as provided in Section 620.21.
725.55.10. For other applications, conductors of Class 2 and Class 3 circuits shall be separated by at least 50 mm (2 in) from conductors of any electric light, power, Class 1 non- power-limited fire alarm, or medium power network-powered broadband communications circuits unless one of the following conditions are met:
725.55.10.1. Either (a) all of the electric light, power, Class 1, non-power-limited fire alarm, and medium power network-powered broadband circuit conductors or (b) all of the Class 2 and Class 3 circuit conductors are in a raceway or in metal sheathed, metal clad, non-metallic-sheathed, or Type UF cables.
725.55.10.2. All of the electric light, power, Class 1 non-power-limited fire alarm, and medium power network-powered broadband communication circuit conductors are permanently separated from all of the Class 2 and Class 3 circuit conductors by a continuous and firmly fixed nonconductor, such as porcelain tubes or flexible tubing, in addition to the insulation on the conductors.
725.56. Installation of Conductors of Different Circuits in the Same Cable, Enclosure, or Raceway.
725.56.1 Two or More Class 2 Circuits. Conductors of two or more Class 2 circuits shall be permitted within the same cable, enclosure or raceway.
725.56.2 Two or More Class 3 Circuits. Conductors of two or more Class 3 circuits shall be permitted within the same cable, enclosure or raceway.
725.56.3. Class 2 Circuits with Class 3 Circuits. Conductors of one or more Class 2 circuits shall be permitted within the same cable, enclosure or raceway with conductors of Class 3 circuits, provided that the insulation of the Class 2 circuit conductors in the cable, enclosure or raceway is at least that required for Class 3 circuits.
725.56.4 Class 2 and Class 3 Circuits with Communications Circuits.
725.56.4.1. Class 2 and Class 3 circuit conductors shall be permitted in the same cable with communications circuits in which case the Class 2 and Class 3 circuits shall be classified as communications circuits and shall be installed in accordance with the requirements of Article 800. The cables shall be listed as communications cables or multipurpose cables.
725.56.4.2. Cables constructed of individually listed Class 2, Class 3 and communications cables under a common jacket shall be permitted to be classified as communications cables. The fire-resistance rating of the composite cable shall be determined by the performance of the composite cable.
725.56.5. Class 2 or Class 3 Cables with Other Circuit Cables. Jacketed cables of Class 2 or Class 3 circuits shall be permitted in the same enclosure or raceway with jacketed cables of any of the following:

(a) Power-limited fire alarm systems in compliance with Article 760.

(b) Nonconductive and conductive optical fiber cables in compliance with Article 770.

(c) Communications circuits in compliance with Article 800.

(d) Community antenna television and radio distribution systems in compliance with Article 820.

(e)Low power network-powered broadband communications in compliance with Article 830.

725.57. Installation of Circuit Conductors Extending Beyond One Building. Where Class 2 or Class 3 circuit conductors extend beyond one building and are run so as to be subject to accidental contact with electric light or power conductors operating over 300 volts to ground, or are exposed to lightning on inter building circuits on the same premise, the requirements of the following shall also apply:

(a) Sections 800.10, 800.12, 800.13, 800.31, 800.32, 800.33 and 800.40 for other than coaxial conductors.

(b) Sections 820.10, 820.33 and 820.40 for coaxial conductors.

725.58. Support of Conductors. Class 2 or Class 3 circuit conductors shall not be strapped, taped or attached by any means to the exterior of any conduit or other raceway as a means of support. These conductors shall be permitted to be installed as permitted by Section 300.11(b)(2).

760.54. Installation of Conductors and Equipment In Cables, Compartments, Cable Trays, Enclosures, Manholes, Outlet Boxes, Device Boxes and Raceways for Power-Limited Circuits.

Conductors and equipment for power-limited fire alarm circuits shall be installed in accordance with Sections 760.55 through 760.58.

760.55. Separation from Electric Light, Power, Class 1, NPLFA, and Medium Power Network-Powered Broadband Communications Circuit Conductors.

760.55.1. Power-limited fire alarm circuit cables and conductors shall not be placed in any cable, cable tray, compartment, enclosure, manhole, outlet box, device box, raceway, or similar fitting with conductors of electric light, power, Class 1, non-power-limited fire alarm circuits, and medium power network-powered broadband communications circuits unless permitted by 760.55.2 through 760.55.7 below.

760.55.2. Power-limited fire alarm circuit cables shall be permitted to be installed together with Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits when they are separated by a barrier.

760.55.3. In enclosures, power-limited fire alarm circuits shall be permitted to be installed in a raceway within the enclosure to separate them from Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits.

760.55.4. Power-limited fire alarm conductors in compartments, enclosures, device boxes, outlet boxes, or similar fittings shall be permitted to be installed with Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits where they are introduced solely to connect the equipment connected to Class 2 and Class 3 circuits, and

760.55.4.1. The electric light, power, Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuit conductors are routed to maintain a minimum of 6 mm (0.25 in) separation form the conductors or cables of Class 2 and Class 3 circuits, or

760.55.4.2. The circuit conductors operate at 150 volts or less to ground and also comply with one of the following:

(a) The fire alarm power-limited circuits are installed using Type FPL, FPLR, FPLP or permitted substitute cables, provided these power-limited cable conductors extending beyond the jacket are separated by a minimum of 6 mm (0.25 in) or by a nonconductive sleeve or nonconductive barrier from all other conductors, or

(b) The power-limited fire alarm circuit conductors are installed as non-power-limited circuits in accordance with Section 760.25.

760.55.5. Power-limited fire alarm circuit conductors entering compartments, enclosures, device boxes, outlet boxes, or similar fittings shall be permitted to be installed with Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits where they are introduced solely to connect the equipment connected to power-limited fire alarm circuits or to other circuits controlled by the fire alarm system to which the other conductors in the enclosure are connected and if they must enter an enclosure that is provided with a single opening, they shall be permitted to enter through a single fitting (such as a tee) provided the conductors are separated from the conductors of the other circuits by a continuous and firmly fixed nonconductor, such as flexible tubing.

760.55.6. In hoistways, power-limited fire alarm circuit conductors shall be installed in rigid metal conduit, rigid non-metallic conduit, intermediate metal conduit or electrical metallic tubing. For elevators or similar equipment, these conductors shall be permitted to be installed as provided in Section 620.21.

760.55.7. For other applications power-limited fire alarm circuit conductors shall be separated by at least 50 mm (2 in) from conductors of any electric light, power, Class 1 non-power-limited fire alarm, or medium power network-powered broadband communications circuits unless one of the following conditions are met:

760.55.7.1. Either (a) all of the electric light, power, Class 1, non-power-limited fire alarm, and medium power network-powered broadband circuit conductors or (b) all of the power-limited fire alarm circuit conductors are in a raceway or in metal sheathed, metal clad, nonmetallic-sheathed, or Type UF cables.

760.55.7.2. All of the electric light, power, Class 1 non-power-limited fire alarm, and medium power network-powered broadband communication circuit conductors are permanently separated from all of the power-limited fire alarm circuit conductors by a continuous and firmly fixed nonconductor, such as porcelain tubes or flexible tubing, in addition to the insulation on the conductors.

760.56. Installation of Conductors of Different PLFA Circuits, Class 2, Class 3 and Communications Circuits in the Same Cable, Enclosure, or Raceway.

760.56.1 Two or More PLFA Circuits. Cable and conductors of two or more power-limited fire alarm circuits, communications circuits or Class 3 circuits shall be permitted within the same cable, enclosure or raceway.

760.56.2. Class 2 Circuits with PLFA Circuits. Conductors of one or more Class 2 circuits shall be permitted within the same cable, enclosure or raceway with conductors of power-limited fire alarm circuits, provided that the insulation of the Class 2 circuit conductors in the cable, enclosure or raceway is at least that required by the power-limited fire alarm circuits.

760.56.3. Low Power Network-Powered Broadband Communications Cables and PLFA Cables. Low power network-powered broadband communication circuits shall be permitted in the same enclosure or raceway with PLFA cables.

760.57. Support of Conductors. Power-limited fire alarm circuit conductors shall not be strapped, taped or attached by any means to the exterior of any conduit or other raceway as a means of support.

760.58. Conductor Size. Conductors of No. 26 shall only be permitted where spliced with a connector listed as suitable for No. 26 to No. 24 or larger conductors that are terminated on equipment or where the No. 26 conductors are terminated on equipment listed as suitable for No. 26 conductors. Single conductors shall not be smaller than No. 18.

SUBSTANTIATION: The Exceptions are changed to positive code language in compliance with 3.1.4.2 of the Style Manual. In accordance with the Panel Statement for this Proposal, the wording and arrangement have been modified to completely and clearly reflect all the requirements and permitted methods. Section 760-55 for fire alarm cables which parallels the requirements of Section 725-54 for Class 2 and Class 3 wiring has been similarly changed for consistency of presentation. There have been no changes in the technical requirements.

PANEL ACTION: Accept in Principle.

Revise the recommendation to read as follows:

725.54. Installation of Conductors and Equipment In Cables, Compartments, Cable Trays, Enclosures, Manholes, Outlet Boxes, Device Boxes and Raceways for Class 2 and Class 3 Circuits.

Conductors and equipment for Class 2 and Class 3 circuits shall be installed in accordance with Sections 725.55 through 725.58.

725.55. Separation from Electric Light, Power, Class 1, Non-Power-Limited Fire Alarm Circuit Conductors, and Medium Power Network-Powered Broadband Communications Cables.

725.55.1. Cables and conductors of Class 2 and Class 3 circuits shall not be placed in any cable, cable tray, compartment, enclosure, manhole, outlet box, device box, raceway, or similar fitting with conductors of electric light, power, Class 1, non-power-limited fire alarm circuits, and medium power network-powered broadband communications circuits unless permitted by 725.55.2 through 725.55.10 below.

725.55.2. Class 2 and Class 3 circuits shall be permitted to be installed together with Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits ~~when~~ where they are separated by a barrier.

725.55.3. In enclosures, Class 2 and Class 3 circuits shall be permitted to be installed in a raceway to separate them from Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits.
725.55.4. Class 2 and Class 3 circuit conductors in compartments, enclosures, device boxes, outlet boxes, or similar fittings shall be permitted to be installed with electric light, power, Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits where they are introduced solely to connect the equipment connected to Class 2 and Class 3 circuits, and
725.55.4.1. The electric light, power, Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuit conductors are routed to maintain a minimum of 6 mm (0.25 in) separation ~~form~~ from the conductors ~~or~~ and cables of Class 2 and Class 3 circuits, or
725.55.4.2. The circuit conductors operate at 150 volts or less to ground and also comply with one of the following:
(a) The Class 2 and Class 3 circuits are installed using Type CL3, CL3R, or CL3P or permitted substitute cables, provided these Class 3 cable conductors extending beyond the jacket are separated by a minimum of 6 mm (0.25 in) or by a nonconductive sleeve or nonconductive barrier from all other conductors, or
(b) The Class 2 and Class 3 circuit conductors are installed as a Class 1 circuit in accordance with Section 725.21.
725.55.5. Class 2 and Class 3 circuit conductors entering compartments, enclosures, device boxes, outlet boxes, or similar fittings shall be permitted to be installed with Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits where they are introduced solely to connect the equipment connected to Class 2 and Class 3 circuits and if they must enter an enclosure that is provided with a single opening, they shall be permitted to enter through a single fitting (such as a tee) provided the conductors are separated from the conductors of the other circuits by a continuous and firmly fixed nonconductor, such as flexible tubing.
725.55.6. Underground Class 2 and Class 3 circuit conductors in a manhole shall be permitted to be installed with Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits where one of the following conditions is met.
725.55.6.1. The electric light, power, Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuit conductors are in a metal-enclosed cable or Type UF cable.
725.55.6.2. The Class 2 and Class 3 circuit conductors are permanently and effectively separated from the conductors of other circuits by a continuous and firmly fixed nonconductor, such as flexible tubing, in addition to the insulation or covering on the wire.
725.55.6.3. The Class 2 and Class 3 circuit conductors are permanently and effectively separated from conductors of the other circuits and securely fastened to racks, insulators, or other approved supports.
725.55.7. Class 2 and Class 3 conductors as permitted by Section 780-6(a) shall be permitted to be installed in accordance with Article 780.
725.55.8. Class 2 and Class 3 circuit conductors shall be permitted to be installed in cable trays, where the conductors of the electric light, Class 1 and non-power-limited fire alarm circuits are separated by a solid fixed barrier of a material compatible with the cable tray or where the Class 2 or Class 3 circuits are installed in Type MC cable.
725.55.9. In hoistways, Class 2 or Class 3 circuit conductors shall be installed in rigid metal conduit, rigid nonmetallic conduit, intermediate metal conduit, liquidtight flexible nonmetallic conduit or electrical metallic tubing. For elevators or similar equipment, these conductors shall be permitted to be installed as provided in Section 620.21.
725.55.10. For other applications, conductors of Class 2 and Class 3 circuits shall be separated by at least 50 mm (2 in) from conductors of any electric light, power, Class 1 non- power-limited fire alarm, or medium power network-powered broadband communications circuits unless one of the following conditions are met:
725.55.10.1. Either (a) all of the electric light, power, Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuit conductors or (b) all of the Class 2 and Class 3 circuit conductors are in a raceway or in metal sheathed, metal clad, non-metallic-sheathed, or Type UF cables.
725.55.10.2. All of the electric light, power, Class 1 non-power-limited fire alarm, and medium power network-powered broadband communications circuit conductors are permanently separated from all of the Class 2 and Class 3 circuit conductors by a continuous and firmly fixed nonconductor, such as porcelain tubes or flexible tubing, in addition to the insulation on the conductors.
725.56. Installation of Conductors of Different Circuits in the Same Cable, Enclosure, or Raceway.
725.56.1 Two or More Class 2 Circuits. Conductors of two or more Class 2 circuits shall be permitted within the same cable, enclosure or raceway.
725.56.2 Two or More Class 3 Circuits. Conductors of two or more Class 3 circuits shall be permitted within the same cable, enclosure or raceway.
725.56.3. Class 2 Circuits with Class 3 Circuits. Conductors of one or more Class 2 circuits shall be permitted within the same cable, enclosure or raceway with conductors of Class 3 circuits, provided that the insulation of the Class 2 circuit conductors in the cable, enclosure or raceway is at least that required for Class 3 circuits.
725.56.4 Class 2 and Class 3 Circuits with Communications Circuits.
725.56.4.1. Class 2 and Class 3 circuit conductors shall be permitted in the same cable with communications circuits in which case the Class 2 and Class 3 circuits shall be classified as communications circuits and shall be installed in accordance with the requirements of Article 800. The cables shall be listed as communications cables or multipurpose cables.
725.56.4.2. Cables constructed of individually listed Class 2, Class 3 and communications cables under a common jacket shall be permitted to be classified as communications cables. The fire-resistance rating of the composite cable shall be determined by the performance of the composite cable.
725.56.5. Class 2 or Class 3 Cables with Other Circuit Cables. Jacketed cables of Class 2 or Class 3 circuits shall be permitted in the same enclosure or raceway with jacketed cables of any of the following:
(a) Power-limited fire alarm systems in compliance with Article 760.
(b) Nonconductive and conductive optical fiber cables in compliance with Article 770.
(c) Communications circuits in compliance with Article 800.
(d) Community antenna television and radio distribution systems in compliance with Article 820.
(e) Low power network-powered broadband communications in compliance with Article 830.
725.57. Installation of Circuit Conductors Extending Beyond One Building. Where Class 2 or Class 3 circuit conductors extend beyond one building and are run so as to be subject to accidental contact with electric light or power conductors operating over 300 volts to ground, or are exposed to lightning on inter building circuits on the same premise, the requirements of the following shall also apply:
(a) Sections 800.10, 800.12, 800.13, 800.31, 800.32, 800.33 and 800.40 for other than coaxial conductors.
(b) Sections 820.10, 820.33 and 820.40 for coaxial conductors.
725.58. Support of Conductors. Class 2 or Class 3 circuit conductors shall not be strapped, taped or attached by any means to the exterior of any conduit or other raceway as a means of support. These conductors shall be permitted to be installed as permitted by Section 300.11(b)(2).
760.54. Installation of Conductors and Equipment In Cables, Compartments, Cable Trays, Enclosures, Manholes, Outlet Boxes, Device Boxes and Raceways for Power-Limited Circuits.
Conductors and equipment for power-limited fire alarm circuits shall be installed in accordance with Sections 760.55 through 760.58.
760.55. Separation from Electric Light, Power, Class 1, NPLFA, and Medium Power Network-Powered Broadband Communications Circuit Conductors.
760.55.1. Power-limited fire alarm circuit cables and conductors shall not be placed in any cable, cable tray, compartment, enclosure, manhole, outlet box, device box, raceway, or similar fitting with conductors of electric light, power, Class 1, non-power-limited fire alarm circuits, and medium power network-powered broadband communications circuits unless permitted by 760.55.2 through 760.55.7 below.
760.55.2. Power-limited fire alarm circuit cables shall be permitted to be installed together with Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits ~~when~~ where they are separated by a barrier.
760.55.3. In enclosures, power-limited fire alarm circuits shall be permitted to be installed in a raceway within the enclosure to separate them from Class 1, non-power-limited fire alarm, and

medium power network-powered broadband communications circuits.
760.55.4. Power-limited fire alarm conductors in compartments, enclosures, device boxes, outlet boxes, or similar fittings shall be permitted to be installed with electric light, power, Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits where they are introduced solely to connect the equipment connected to Class 2 and Class 3 circuits, and
760.55.4.1. The electric light, power, Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuit conductors are routed to maintain a minimum of 6 mm (0.25 in) separation ~~form~~ from the conductors ~~or~~ and cables of Class 2 and Class 3 circuits, or
760.55.4.2. The circuit conductors operate at 150 volts or less to ground and also comply with one of the following:
(a) The fire alarm power-limited circuits are installed using Type FPL, FPLR, FPLP or permitted substitute cables, provided these power-limited cable conductors extending beyond the jacket are separated by a minimum of 6 mm (0.25 in) or by a nonconductive sleeve or nonconductive barrier from all other conductors, or
(b) The power-limited fire alarm circuit conductors are installed as non-power-limited circuits in accordance with Section 760.25.
760.55.5. Power-limited fire alarm circuit conductors entering compartments, enclosures, device boxes, outlet boxes, or similar fittings shall be permitted to be installed with electric light, power, Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuits where they are introduced solely to connect the equipment connected to power-limited fire alarm circuits or to other circuits controlled by the fire alarm system to which the other conductors in the enclosure are connected and if they must enter an enclosure that is provided with a single opening, they shall be permitted to enter through a single fitting (such as a tee) provided the conductors are separated from the conductors of the other circuits by a continuous and firmly fixed nonconductor, such as flexible tubing.
760.55.6. In hoistways, power-limited fire alarm circuit conductors shall be installed in rigid metal conduit, rigid non-metallic conduit, intermediate metal conduit, liquidtight flexible nonmetallic conduit or electrical metallic tubing. For elevators or similar equipment, these conductors shall be permitted to be installed as provided in Section 620.21.
760.55.7. For other applications power-limited fire alarm circuit conductors shall be separated by at least 50 mm (2 in) from conductors of any electric light, power, Class 1 non-power-limited fire alarm, or medium power network-powered broadband communications circuits unless one of the following conditions are met:
760.55.7.1. Either (a) all of the electric light, power, Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuit conductors or (b) all of the power-limited fire alarm circuit conductors are in a raceway or in metal sheathed, metal clad, nonmetallic-sheathed, or Type UF cables.
760.55.7.2. All of the electric light, power, Class 1, non-power-limited fire alarm, and medium power network-powered broadband communications circuit conductors are permanently separated from all of the power-limited fire alarm circuit conductors by a continuous and firmly fixed nonconductor, such as porcelain tubes or flexible tubing, in addition to the insulation on the conductors.
760.56. Installation of Conductors of Different PLFA Circuits, Class 2, Class 3 and Communications Circuits in the Same Cable, Enclosure, or Raceway.
760.56.1 Two or More PLFA Circuits. Cable and conductors of two or more power-limited fire alarm circuits, communications circuits or Class 3 circuits shall be permitted within the same cable, enclosure or raceway.
760.56.2. Class 2 Circuits with PLFA Circuits. Conductors of one or more Class 2 circuits shall be permitted within the same cable, enclosure or raceway with conductors of power-limited fire alarm circuits, provided that the insulation of the Class 2 circuit conductors in the cable, enclosure or raceway is at least that required by the power-limited fire alarm circuits.
760.56.3. Low Power Network-Powered Broadband Communications Cables and PLFA Cables. Low power network-powered broadband communications circuits shall be permitted in the same enclosure or raceway with PLFA cables.
760.57. Support of Conductors. Power-limited fire alarm circuit conductors shall not be strapped, taped or attached by any means to the exterior of any conduit or other raceway as a means of support.
760.58. Conductor Size. Conductors of No. 26 shall only be permitted where spliced with a connector listed as suitable for No. 26 to No. 24 or larger conductors that are terminated on equipment or where the No. 26 conductors are terminated on equipment listed as suitable for No. 26 conductors. Single conductors shall not be smaller than No. 18.
PANEL STATEMENT: The changes made to the recommended text are editorial in nature and provide consistent language.
Revisions have also been made to reflect the intent of the recommendation in Comment 16-73 by adding "liquidtight flexible nonmetallic conduit" in appropriate places.

16- 74 - (725-54(e)): Accept in Principle
SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardant Chemicals Assoc.
COMMENT ON PROPOSAL NO: 16-80
RECOMMENDATION: Continue accepting this proposal in principle, by retaining the phrase: "Abandoned cables, not intended for future use shall not be permitted to remain."
SUBSTANTIATION: There is a potential for increased fire hazard or fire risk when any cable, irrespective of whether it is or is not limited combustible, remains as fuel load unnecessarily once it has been taken out of use. Materials that are limited combustible can also burn (i.e., they are not noncombustible) and also increase the fire load. Furthermore, all abandoned cables can also affect the safety of plenums because of their weight. There is, thus, no justification for permitting any cable to remain in a plenum once it is abandoned and not intended for future use.
PANEL ACTION: Accept in Principle.

SUBMITTER: Robert W. Jensen, dbi-Telecommunications Infrastructure Design
COMMENT ON PROPOSAL NO: 16-80
RECOMMENDATION: Abandoned cables shall not be permitted to remain.
SUBSTANTIATION: We recognize the Panel action to accept our proposal in principle, broadened it's impact from requiring cable to be removed from ducts, plenums, and other spaces used for environmental air to also include risers and hollow spaces. We support this action in the interest of fire safety. We also removed the phrase "for future use" because it is redundant.

PANEL ACTION: Accept in Principle.
Revise the second sentence of 725-3(a) in the panel action of Proposal 16-80 to read as follows:
The accessible portion of abandoned Class 2, Class 3 and PLTC cables shall not be permitted to remain.
PANEL STATEMENT: The intent is not to remove cables where it would be extremely difficult or damaging to the building or the remaining cables.

16- 84 - (725-54(e), Exception): Accept
SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardant Chemicals Assoc.
COMMENT ON PROPOSAL NO: 16-74
RECOMMENDATION: Continue rejecting the exception for permitting cable to be listed as limited combustible to remain in plenums, in particular CL2P-50 and CL3P-50.
SUBSTANTIATION: Materials that are limited combustible can burn (i.e., they are not noncombustible) and increase the fire load. Therefore, there is a potential for increased fire hazard or fire risk when any cable irrespective of whether it is or is not limited combustible, remains as fuel load unnecessarily once it has been taken out of use. Furthermore, all abandoned cables can also affect the safety of plenums because of their weight. There is, thus, no justification for permitting a "limited combustible" cable to remain in a plenum once it is abandoned and not intended for future use.
PANEL ACTION: Accept.

SUBMITTER: Stanley D. Kahn, Tri-City Electric Co., Inc.
COMMENT ON PROPOSAL NO: 16-81
RECOMMENDATION: Reconsider the proposal but revise the wording including Approved Proposals 16-82 and 16-83, substitute the wording in parallel Sections 760-61, 770-53, 800-53, 820-53 and 830-53 and move Section 800-52(d) into Section 800.53 renumbering 800-53(e) as 800-52(d) to read as follows:
725.61. Applications of Listed Class 2, Class 3 and PLTC Cables. Class 2, Class 3 and PLTC Cables shall comply with the requirements described in any of the following Sections: 725.61.1 through 725.61.6, or where cable substitutions are made as shown in Section 725.61.7.
725.61.1. Plenum. Cables installed in ducts, plenums, and other spaces used for environmental air shall be Type CL2P or CL3P. Abandoned cables shall not be permitted to remain. Listed wires and cables installed in compliance with Section 300.22 shall be permitted.
725.61.2. Riser. Cables installed in risers shall be as described in any of the following Sections: 725.61.2.1 through 725.61.2.3.
725.61.2.1. Cables installed in vertical runs and penetrating more than one floor, or cables installed in vertical runs in a shaft, shall be Type CL2R or CL3R. Floor penetrations requiring Type CL2R or CL3R shall contain only cables suitable for riser or plenum use. Abandoned cables shall not be permitted to remain.
725.61.2.2. Other cables as covered in Table 725.61 and other listed wiring methods as covered in Chapter 3, shall be installed in metal raceways or located in a fireproof shaft having firestops at each floor.
725.61.2.3. Type CL2, CL3, CL2X and CL3X cables shall be permitted in one- and two-family dwellings.
FPN: *See Section 300.21 for firestop requirements for floor penetrations.*
725.61.3. Cable Trays. Cables installed in cable trays outdoors shall be Type PLTC. Cables installed in cable trays indoors shall be Types PLTC, CL3P, CL3R, CL3, CL2P, CL2R and CL2.
FPN: *See Section 800.52(d) for cables permitted in cable trays.*
725.61.4. Hazardous (Classified) Locations. Cables installed in hazardous locations shall be as described in any of the following Sections: 725.61.4.1 through 725.61.4.4.
725.61.4.1. Cables installed in hazardous (classified) locations shall be Type PLTC. Where the use of Type PLTC cable is permitted by Sections 501.4(b), 502.4(b) and 504.20, the cable shall be installed in cable trays, in raceways supported by messenger wire or otherwise adequately supported and mechanically protected by angles, struts, channels or other mechanical means. The cable shall be permitted to be directly buried where the cable is listed for this use.
725.61.4.2. Wiring for Class 2 circuits as permitted by Section 501.4(b) *Exception* shall be permitted.
725.61.4.3. Conductors in Type PLTC cables used for Class 2 thermocouple circuits shall be permitted to be any of the materials used for thermocouple extension wire.
725.61.4.4. In industrial establishments where the conditions of maintenance and supervision ensure that only qualified persons will service the installation, and where the cable is not subject to physical damage, Type PLTC cable that complies with the crush and impact requirements of Type MC cable and is identified for such use shall be permitted as open wiring between cable tray and utilization equipment in lengths not to exceed 15 m (50 ft). The cable shall be supported and protected against physical damage using mechanical protection such as dedicated struts, angles or channels. The cable shall be supported and secured at intervals not exceeding 1.75 m (6 ft).
725.61.5. Other Wiring Within Buildings. Cables installed in building locations other than those covered in Sections 725.65.1 through 725.61.4 shall be as described in any of the following Sections: 725.65.5.1 through 725.65.6. Abandoned cables in hollow spaces shall not be permitted to remain.
725.61.5.1. Type CL2 or CL3 shall be permitted.
725.61.5.2. Type CL2X or CL3X shall be permitted to be installed in a raceway, or other wiring methods covered in Chapter 3.
725.61.5.3. Cables shall be permitted to be installed in nonconcealed spaces where the exposed length of cable does not exceed 3 m (10 ft).
725.61.5.4. Listed Type CL2X cables less than 6 mm (0.25 in) in diameter and listed Type CL3X cables less than 6 mm (0.25 in) in

diameter shall be permitted to be installed in one- and two-family dwellings.
725.61.5.5. Listed Type CL2X cables less than 6 mm (0.25 in) in diameter and listed Type CL3X cables less than 6 mm (0.25 in) in diameter shall be permitted to be installed in nonconcealed spaces in multi-family dwellings.
725.61.5.6. Type CMUC undercarpet communications wires and cables shall be permitted to be installed under carpet.
725.61.6. Cross-Connect Arrays. Type CL2 or CL3 conductors or cables shall be used for cross-connect arrays.
725.61.7. Class 2 and Class 3 Cable Uses and Permitted Substitutions. The uses and permitted substitutions for Class 2 and Class 3 cables listed in Table 725.61 shall be considered suitable for the purpose and shall be permitted.

Insert revised Table 725-61. Cable Uses and Permitted Substitutions *in accordance with Accepted Proposal 16-82.*

FPN: For information on Types CMP, CMR, CMG, CM and CMX cables, see Section 800.51.

Insert revised Figure 725-61. Cable Substitution Hierarchy. *In accordance with Accepted Proposal 16-82 and Comment on Affirmative by Stanley Kaufman.*

(Artwork not provided)

760.61. Applications of Listed PLFA Cables.
PLFA Cables shall comply with the requirements described in any of the following Sections: 760.61.1 through 760.61.3,or
where cable substitutions are made as shown in Section 760.61.4.
760.61.1. Plenum. Cables installed in ducts, plenums, and other spaces used for environmental air shall be Type FPLP. Abandoned cables shall not be permitted to remain. Types FPLP, FPLR and FPL cable installed in compliance with Section 300.22 shall be permitted.
760.61.2. Riser. Cables installed in risers shall be as described in any of the following Sections: 760.61.2.1 through 760.61.2.3.
760.61.2.1. Cables installed in vertical runs and penetrating more than one floor, or cables installed in vertical runs in a shaft, shall be Type FPLR. Floor penetrations requiring Type FPLR shall contain only cables suitable for riser or plenum use. Abandoned cables shall not be permitted to remain.
760.61.2.2. Other cables shall be installed in metal raceways or located in a fireproof shaft having firestops at each floor.
760.61.2.3. Type FPL cable shall be permitted in one- and two-family dwellings.
FPN: *See Section 300.21 for firestop requirements for floor penetrations.*
760.61.3. Other Wiring Within Buildings. Cables installed in building locations other than those covered in Sections 760.61.1 or 760.61.2 shall be as described in any of the following Sections: 760.61.3.1 through 760.61.3.4. Abandoned cables in hollow spaces shall not be permitted to remain
760.61.3.1. Type FPL shall be permitted.
760.61.3.2. Cables shall be permitted to be installed in raceways.
760.61.3.3. Cables specified in Chapter 3 and meet the requirements of Sections 760.71.1 and 760.71.2 shall be permitted to be installed in nonconcealed spaces where the exposed length of cable does not exceed 3 m (10 ft).
760.61.3.4. A portable fire alarm system provided to protect a stage or set when not in use shall be permitted to use wiring methods in accordance with Section 530.12.
760.61.4. Fire Alarm Cable Uses and Permitted Substitutions. The uses and permitted substitutions for fire alarm cables listed in Table 760.61 shall be considered suitable for the purpose and shall be permitted.

Insert revised Table 760-61. Cable Uses and Permitted Substitutions

FPN: For information on multipurpose cables (Types MPP, MPR, MPG, MP) and communications cables (Types CMP, CMR, CMG, CM), see Section 800.501.

770.53. Applications of Listed Optical Fiber Cables and Raceways.
Nonconductive and conductive optical fiber cables shall comply with the requirements any of the following Sections: 770.53.1
through 770.53.5 or where cable substitutions are made as shown in Section 770-53.6.
770.53.1. Plenum. Cables installed in ducts, plenums, and other spaces used for environmental air shall be Type OFNP or OFCP. Abandoned cables shall not be permitted to remain. Types OFNR, OFCR, OFNG, OFN, OFCG and OFC cables installed in compliance with Section 300.22 shall be permitted. Listed plenum optical fiber raceways shall be permitted to be installed in ducts and plenums as described in Section 300-22(b) and in other spaces used for environmental air as described in Section 300-22(c). Only Type OFNP cable shall be permitted to be installed in these raceways.
770.53.2. Riser. Cables installed in risers shall be as described in any of the following Sections: 800.53.2.1 through 800.53.2.3.
770.53.2.1. Cables installed in vertical runs and penetrating more than one floor, or cables installed in vertical runs in a shaft, shall be Types OFNR or OFCR. Floor penetrations requiring Types OFNR or OFCR shall contain only cables suitable for riser or plenum use. Abandoned cables shall not be permitted to remain. Listed riser optical fiber raceways shall be permitted to be installed in vertical riser runs in a shaft from floor to floor. Only Types OFNR and OFNP cables shall be permitted to be installed in these raceways.
770.53.2.2. Listed optical fiber cables shall be permitted to be encased in a metal raceway or located in a fireproof shaft having firestops at each floor.
770.53.2.3. Type OFNG, OFN, OFCG and OFC cable shall be permitted in one- and two-family dwellings.
FPN: *See Section 300.21 for firestop requirements for floor penetrations.*
770.53.3. Other Wiring Within Buildings. Cables installed in building locations other than the locations covered in Sections 770.53.1 and 770.53.2 shall be Type OFNG, OFN, OFCG or OFC. Such cables shall be permitted to be installed in listed general-purpose optical fiber raceways.
770.53.4. Hazardous (Classified) Locations. Cables installed in hazardous (classified) locations shall be any type indicated in Table 770.53.
770.53.5. Cable Trays. Optical fiber cables of the types listed in Table 770.50 shall be permitted to be installed in cable trays.
FPN: *It is not the intent to require that these optical fiber cables be listed specifically for use in cable trays.*
770.53.6. Cable Substitutions. The substitutions for optical fiber cables listed in Table 770.53 shall be permitted.

Insert Table 770.53. Cable Substitution *as modified by Stan Kaufman's*
Comment.

Insert Figure 770.53. Cable Substitution Hierarchy.
(Artwork not provided)

800.53. Applications of Listed Communications Wires and Cables, and Communications Raceways.
Communications wires and cables shall comply with the requirements any of the following Sections: 800.53.1 through 800.53.7
or where cable substitutions are made as shown in Section 800-53.8
800.53.1. Plenum. Cables installed in ducts, plenums, and other spaces used for environmental air shall be Type CMP. Abandoned cables shall not be permitted to remain. Types CMP, CMR, CMG, CM and CMX and communications wire installed in compliance with Section 300.22 shall be permitted. Listed plenum communications raceways shall be permitted to be installed in ducts and plenums as described in Section 300-22(b) and in other spaces used for environmental air as described in Section 300-22(c). Only Type CMP cable shall be permitted to be installed in these raceways.
800.53.2. Riser. Cables installed in risers shall be as described in any of the following Sections: 800.53.2.1 through 800.53.2.3.
800.53.2.1. Cables installed in vertical runs and penetrating more than one floor, or cables installed in vertical runs in a shaft, shall be Type CMR. Floor penetrations requiring Type CMR shall contain only cables suitable for riser or plenum use. Abandoned cables shall not be permitted to remain. Listed riser communications raceways shall be permitted to be installed in vertical riser runs in a shaft from floor to floor. Only Type CMR and CMP cables shall be permitted to be installed in these raceways.
800.53.2.2. Listed communications cables shall be encased in a metal raceway or located in a fireproof shaft having firestops at each floor.
800.53.2.3. Type CM and CMX cable shall be permitted in one- and two-family dwellings.
FPN: *See Section 800.52.2 for firestop requirements for floor penetrations.*
800.53.3. Distributing Frames and Cross-connect Arrays. Listed communications wire and Types CMP, CMR, CMG, and CM

communications cables shall be used in distributing frames and cross-connect arrays.
800.53.4. Cable Trays. Types MPP, MPR, MPG, and MP multipurpose cables and Types CMP, CMR, CMG, and CM communications cables shall be permitted to be installed in cable trays.
800.53.5. Other Wiring Within Buildings. Cables installed in building locations other than the locations covered in Sections 800.53.1, through 800.53.4 shall be as installed described in any of the following Sections: 800.53.5.1 through 800.53.5.6.
800.53.5.1. Cables shall be Type CMG or Type CM. Listed communications general purpose raceways shall be permitted. Only Type CMG, CM, CMR or CMP cables shall be permitted to be installed in general purpose communications raceways.
800.53.5.2. Listed communications wires that are enclosed in a raceway of a type included in Chapter 3 shall be permitted.
800.53.5.3. Type CMX communications cable shall be permitted to be installed in nonconcealed spaces where the exposed length of cable does not exceed 3 m (10 ft).
800.53.4.4. Type CMX communications cables less than 6 mm (0.25 in) in diameter shall be permitted to be installed in one- and two-family dwellings.
800.53.4.5. Type CMX communications cables less than 6 mm (0.25 in) in diameter shall be permitted to be installed in nonconcealed spaces in multi-family dwellings.
800.53.4.6. Type CMUC under-carpet communications wires and cables shall be permitted to be installed under carpet.
800.53.5. Hybrid Power and Communications Cable. Hybrid power and communications cable listed in accordance with Section 800.51.8 shall be permitted to be installed in one- and two-family dwellings/
800.53.6. Cable Substitutions. The uses and permitted substitutions for communications cables listed in Table 800.53 shall be considered suitable for the purpose and shall be permitted.

Insert Table 800.53. Cable Uses and Permitted Substitutions *as modified below:*

820.53. Applications of Listed CATV Cables.
CATV cables shall comply with the requirements any of the following Sections: 820.53.1 through 820.53.5 or where cable substitutions are made as shown in Section 820-53.6.
820.53.1. Plenum. Cables installed in ducts, plenums, and other spaces used for environmental air shall be Type CATVP. Abandoned cables shall not be permitted to remain. Types CATVP, CATVR, CATV and CATVX cables installed in compliance with Section 300.22 shall be permitted.
820.53.2. Riser. Cables installed in risers shall be as described in any of the following Sections: 800.53.2.1 through 800.53.2.3.
820.53.2.1. Cables installed in vertical runs and penetrating more than one floor, or cables installed in vertical runs in a shaft, shall be Type CATVR. Floor penetrations requiring Type CATVR shall contain only cables suitable for riser or plenum use. Abandoned cables shall not be permitted to remain.
820.53.2.2. Types CATV and CATVX cables shall be permitted to be encased in a metal raceway or located in a fireproof shaft having firestops at each floor.
820.53.2.3. Types CATV and CATVX cables shall be permitted in one- and two-family dwellings.
FPN: *See Section 820.52.2 for firestop requirements for floor penetrations.*
820.53.3. Other Wiring Within Buildings. Cables installed in building locations other than the locations covered in Sections 820.53.1 and 820.53.2 shall be shall be as described in any of the following Sections: 820.53.3.1 through 820.53.3.6. Abandoned cables in hollow spaces shall not be permitted to remain.
820.53.3.1. Type CATV shall be permitted.
820.53.3.2. Type CATVX shall be permitted to be installed in a raceway.
820.53.3.3. Type CATVX shall be permitted to be installed in nonconcealed spaces where the exposed length of cable does not exceed 3 m (10 ft).
820.53.3.4. Type CATVX cables less than 10 mm (0.375 in) in diameter shall be permitted to be installed in one- and two-family dwellings.

Table 800-53. Cable Uses and Permitted Substitutions

Cable Type	Use	References	Permitted Substitutions
CMP	Communications plenum cable	800-53.1	MPP
CMR	Communication riser cable	800-53.2	MPP, CMP, MPR
CMG, CM	Communications general-purpose cable	800-53.5.1	MPP, CMP, MPR, CMR, MPG, MP
CMX	Communications cable, limited use	800-53.3, 53.4 & 53.5	MPP, CMP, MPR, CMR, MPG, MP, CMG, CM

Note: See Figure 800-53, Cable substitution hierarchy.

FPN: For information on Types CMP, CMR, CMG, CM and CMX cables, see Section 800.51.

Insert Figure 800.53. Cable Substitution Hierarchy *as modified by Stan Kaufman's comment.*
(Artwork not provided)

Replace Figure 800.50. Cable Substitution Hierarchy with the following~~Exception No. 5~~

820.53.3.5. Type CATVX cables less than 10 mm (0.375 in) in diameter shall be permitted to be installed in nonconcealed spaces in multi-family dwellings.
820.53.4. Cable Substitutions. The substitution for community antenna television cables listed in Table 820.53 shall be considered suitable for the purpose and shall be permitted.

Insert Table 820.53. Coaxial Cable Uses and Permitted Substitutions

Table 800-50. Cable Markings

Cable Marking	Type	Reference
MPP	Multipurpose plenum cable	800-51(g) and 800-53.1
CMP	Communications plenum cable	800-51(a) and 800-53.1
MPR	Multipurpose riser cable	800-51(g) and 800-53.2)
CMR	Communications riser cable	800-51(b) and 800-53.2
MPG	Multipurpose general-purpose cable	800-51(g) and 800-53.4 & 53.5.1
CMG	Communications general-purpose cable	800-51(c) and 800-53.4 & 53.5.1
MP	Multipurpose general-purpose cable	800-51(g) and 800-53.4 & 53.5.1
CM	Communications general-purpose cable	800-51(d) and 800-53.4 & 53.5.1
CMX	Communications cable, limited use	800-51(e) and 800-53.3, 53.4 & 53.5
CMUC	Under-carpet communications wire and cable	800-51(f) and 800-53.4.6

FPN: *The substitute cables in Table 820.53 are only coaxial-type cables.*

Insert Figure 820.53. Cable Substitution Hierarchy.
(Artwork not provided)

830.55. Low Power Network-Powered Broadband Communications System Wiring Methods.
Low power network-powered broadband systems shall comply with the requirements any of the following Sections: 830.55.1 through 830.55.4.
830.55.1. In Buildings. Low power network-powered broadband communications systems shall be installed within buildings using listed Type BLX or Type BLP network-powered broadband communications low power cables.
830.55.2. Ducts, Plenums and Other Air Handling Spaces. Cables installed in ducts, plenums, and other spaces used for environmental air shall be Type BLP. Abandoned cables shall not be permitted to remain. Types BLX cable installed in compliance with Section 300.22 shall be permitted.
830.55.3. Riser. Cables installed in risers shall be as described in any of the following Sections: 830.55.3.1 through 830.55.3.3.
830.55.3.1. Cables installed in vertical runs and penetrating more than one floor, or cables installed in vertical runs in a shaft, shall be Type BLP or BMR. Floor penetrations requiring Type BMR shall contain only cables suitable for riser or plenum use. Abandoned cables shall not be permitted to remain.
830.55.3.2. Type BLX cables shall be permitted to be encased in a metal raceway or located in a fireproof shaft having firestops at each floor.
830.55.3.3. Type BLX cables less than 10 mm (0.375 in) in diameter shall be permitted in one- and two-family dwellings.
830.55.4. Other Wiring. Cables installed in locations other than the locations covered in Sections 830.55.1 through 830.55.3 shall be as described in any of the following Sections: 830.55.4.1 through 830.55.4.5. Abandoned cables in hollow spaces shall not be permitted to remain.
830.55.4.1. Type BLP or BM shall be permitted.
830.55.4.2. Type BLX shall be permitted to be installed in a raceway.
830.55.4.3. Type BLU cable entering the building from outside shall be permitted to be run in rigid metal conduit or intermediate metal conduit. Such conduits shall be grounded to an electrode in accordance with Section 830.40.2
830.55.4.4. Type BLX cable less than 10 mm (0.375 in) in diameter shall be permitted to be installed in one- and two-family dwellings.
830.55.4.5. Type BLX cable entering the building from outside and terminated at a grounding block or a primary protection location shall be permitted to be installed provided that the length of cable within the building does not exceed 15 m (50 ft).

FPN: *This provision limits the length of Type BLX cable to 15 m (50 ft) while Section 830.30.2 requires that the primary protector, or NIU with integral protection, be located as close as practicable to the point at which the cable enters the building. Therefore, in installations requiring a primary protector, or NIU with integral protection, Type BLX cable may not be permitted to extend 15 m (50 ft) into the building if it is practicable to place the primary protector closer than 15 m (50 ft) to the entrance point.*

SUBSTANTIATION: The Exceptions are changed to positive code language in compliance with 3.1.4.2 of the Style Manual. In accordance with the Panel Statement for this Proposal, the wording and arrangement have been modified to completely and clearly reflect all the requirements and permitted methods. Section 760-61 for fire alarm cables, Section 770-53 for optical fiber cables and raceways, Section 800-53 for communications wiring, Section 820-53 for listed CATV cables and Section 830-53 for low power network-powered broadband communications systems which parallel the requirements of Section 725-61 for Class 2 and Class 3 wiring have been similarly changed for consistency of presentation. There have been no changes in the technical requirements. Section 800-52(d) was incorporated into new Section 800.53 since it is more appropriate to place it there.
PANEL ACTION: Accept.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 22
VOTE ON PANEL ACTION:
AFFIRMATIVE: 22

(Log #1077)

16- 88 - (Table 725-61): Reject
Note: "See Technical Correlating Committee action on Comment 16-98."
SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.
COMMENT ON PROPOSAL NO: 16-82
RECOMMENDATION: This proposal should be rejected, the references to CL2P-50 and CL3P-50 should be deleted from the Table 725-61 and not incorporated into Figure 725-61 and the CL2P-50 and CL3P-50 classifications should not be created.
SUBSTANTIATION: The CL2P-50 and CL3P-50 classifications are unnecessary classification because they are not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}

*"Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are

relevant to the fire risk from plenum cables, as plenum cables are the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}

* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}

* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}

* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.

* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."

* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $- C\,H_2 - + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2\,H_3\,Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2\,H_3\,Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb

generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\ H_2O + 0.5\ N_2 + 1.25\ O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a\ H_b\ O_c\ F_e + (a+b/4-c/2-e/4)\ O_2 + (n+1/2)*e*(1-x) - b/2)\ H_2O = (a-ex/4)\ CO_2 + + ex/4\ CF_4 + e(1-x)\ (HF) + e(1-x)\ n\ H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

VOTE ON PANEL ACTION:

AFFIRMATIVE: 19
NEGATIVE: 2
ABSTENTION: 1

EXPLANATION OF NEGATIVE:

JOHNSON: Limited Combustible Cable. To our knowledge, nothing in the code precludes the use of this cable type as a plenum substitute. No improvements in safety have been demonstrated to warrant the need for limited combustible cables, nor has sufficient evidence has been submitted to justify a special classification for this cable type. The panel's action could be conceived as an endorsement of a material or method by the NEC, which is beyond its scope.

Section 90-1(b) of the NEC states that: "This Code contains provisions that are considered necessary for safety." The addition of the new cable does not fit into this mandate. The fact that the panel did not consider use of this cable as a requirement for any wiring method (it is only optional) supports this point.

Significant and well-documented objections to these proposals have been raised. For example, disagreement exists on the validity and repeatability of limited combustible cable testing. In light of these numerous objections, further study is justified before reaching a conclusion to add this new cable type to the code.

WADEHRA: A. The computerization of offices and homes started to take place in the early eighties necessitating the installation of a high volume of inter-connect cables in the plenum areas. Around the same timeframe, the 1981 NEC was revised to require the use of low flame spread and low smoke cables (UL-910 rated) plenum cables. Accordingly, it can be stated that the bulk of the cables installed are already fully flame retardant and there is no additional need to further tighten the flammability requirement.

B. I am not aware of any recent field fire incidents justifying the use of "Limited Combustion Cables." Besides, no improvements in safety have been demonstrated to warrant the need for limited combustible cables, nor has sufficient evidence been submitted to justify a special classification for this cable type.

C. The 2002 NEC will require the removal of abandoned cables in the plenum areas, which should result in sizable reduction in the number of cables presently installed in the plenums.

D. To our knowledge, nothing in the Code precludes the use of this cable type as a plenum substitute.

E. The NFPA Fire Protection Research Foundation Project developing the classification has not issued its final report. The Interim Report exhibits poor validity and repeatability between the two labs conducting the test. Further study is justified before reaching a conclusion to add this new cable type to the code.

COMMENT ON AFFIRMATIVE:

KAHN: I agree with the panel action recognizing limited combustible cables as meeting existing code requirements and permitting their application for these circuits. It should be noted that the panel approved a permissive use, not a mandatory use. There was extensive discussion and numerous technical

presentations at the panel meeting and the conclusion reached is prudent and consistent with the recognition of new technologies.

KAUFMAN: The Standards Council has given the Technical Committee on Air Conditioning and its standard, NFPA 90A, Standard for the Installation of Air-Conditioning and Ventilating Systems, primary responsibility for fire protection of plenum spaces. The establishment of listing requirements for limited combustible cable in the National Electrical Code facilities choosing a cable which meets the NFPA 90A general rule for materials (cables) in plenums.

Using limited combustible plenum cable is permissive. Panel 16 did not receive any proposals requiring their use. In the panel discussion of limited combustible cables, some panel members were concerned that establishing these cable was a first step and that in later code cycles these cables would be required. Their concern obviously involved the added cost of the high-performance materials currently used in limited combustible cables. I have confidence that panel 16 will not accept any proposals requiring limited combustible cables unless presented with compelling safety issues that we have not yet heard. The panel also heard extensive discussions of the test methods for limited combustible cables. Both the UL and ETL representatives on the panel stated that they had listing programs for limited combustible cable and that the test methods were appropriate for use in their listing programs.

EXPLANATION OF ABSTENTION:

CAUDILL: The Society of the Plastics Industries could not reach a consensus position on this issue.

SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.
COMMENT ON PROPOSAL NO: 16-85
RECOMMENDATION: This proposal should be rejected, the references to CL2P-50 and CL3P-50 should be deleted from the Table 725-71 and the CL23P-50 and CL3P-50 classifications should not be created.
SUBSTANTIATION: The CL2P-50 and CL3P-50 classifications are unnecessary classification because they are not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The CL2P-50 and CL3P-50 classifications are unnecessary classification because they are not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

*"Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}

*"Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are

the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

*NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}

*NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}

*NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}

*Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

*NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.

*Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."

*Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $- C\,H_2 - + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2\,H_3\,Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2\,H_3\,Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb

calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\ H_2O + 0.5\ N_2 + 1.25\ O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a\ H_b\ O_c\ F_e + (a+b/4-c/2-e/4)\ O_2 + (n+1/2)*e*(1-x) - b/2)\ H_2O = (a-ex/4)\ CO_2 + + ex/4\ CF_4 + e(1-x)\ (HF) + e(1-x)\ n\ H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

(Log #1068)

16- 97 - (725-71(b)): Reject

SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.

COMMENT ON PROPOSAL NO: 16-88

RECOMMENDATION: This proposal should be rejected, the new section 725-71(b) should not be created and the CL2P-50 and CL3P-50 classifications should not be created.

SUBSTANTIATION: The CL2P-50 and CL3P-50 classifications are unnecessary classification because they are not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}
* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}
* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.

* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."

* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$C + O_2 = CO_2$

$4\,H + O_2 = 2\,H_2O$

For hydrocarbon fuels: $-C\,H_2- + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2\,H_3\,Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2\,H_3\,Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\,H_2O + 0.5\,N_2 + 1.25\,O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a\,H_b\,O_c\,F_e + (a+b/4-c/2-e/4)\,O_2 + (n+1/2)*e*(1-x) - b/2)\,H_2O = (a-ex/4)\,CO_2 + ex/4\,CF_4 + e(1-x)\,(HF) + e(1-x)\,n\,H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a

material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

(Log #1082)

16- 98 - (725-71(b) (New)): Reject

Note: It was the action of the Technical Correlating Committee that Comments 16-76, 85, 88, 89, 90, 93, 94, 95, 96, 98, 99, 100, 103, 104, 105, 106, 107, 108, 109, 110, 112, 158, 164, 165, 167, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 184, 186, 187, 213, 214, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 236, 238, 239, 278, 279, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 297, 305, 308, 309, 310, 344, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 363, 364, 365 and related Proposals 16-75, 82, 85, 89, 140, 145, 149, 152, 162, 164, 169, 177, 191, 224, 226, 231, 232, 243, 254, 260, 297, 298, 302, 316, 7-23 and 8-16 be reported as "Reject" because the panel's action contains no requirements or specifications for the use of limited combustible cable versus the general cables already specified. Code-Making Panel 16 is directed to address the addition of the cable at an appropriate time when a requirement or unique application limitation for the use of the cable has been established in the NEC. The Technical Correlating Committee notes that it is inappropriate to attempt to include references to all products that do not have a need for specific application rules or products that are permitted but not required by the NEC. Further, the Technical Correlating Committee notes that the NEC does not prohibit the use of limited combustible cable.

SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.

COMMENT ON PROPOSAL NO: 16-89

RECOMMENDATION: This proposal should be rejected, the new section 725-71(b) should not be created and the CL2P-50 and CL3P-50 classifications should not be created.

SUBSTANTIATION: The CL2P-50 and CL3P-50 classifications are unnecessary classifications because they are not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}
* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30%

started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}

* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}

* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}

* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.

* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."

* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $- C\,H_2 - + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2\,H_3\,Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2\,H_3\,Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:
$HNO_3 = 0.5\ H_2O + 0.5\ N_2 + 1.25\ O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a\ H_b\ O_c\ F_e + (a+b/4-c/2-e/4)\ O_2 + (n+1/2)*e*(1-x) - b/2)\ H_2O = (a-ex/4)\ CO_2 + ex/4\ CF_4 + e(1-x)\ (HF) + e(1-x)\ n\ H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

Note: Supporting material is available for review at NFPA Headquarters.

PANEL ACTION: Reject.

PANEL STATEMENT:

The continued acceptance of limited combustible cable will make improved fire safe cable available as an option for users who want an enhanced level of fire safety regardless of whether or not a fire hazard analysis indicates such a cable is needed. These cables will be an option, an option that correlates with basic rule in NFPA 90A, Standard for the Installation of Air-Conditioning and Ventilating Systems for installations in ceiling cavity and raised floor plenums. The basic rule in section 2-3.10.2 Ceiling Cavity Plenum and section 2-3.10.6 Raised Floor Plenum is:

" All materials exposed to the airflow shall be noncombustible or limited combustible and have a maximum smoke developed index of 50."

Continued acceptance of the proposals establishing limited combustible cable in the NEC will not require the installation of limited combustible cable.

The objections to the test methods are an issue for the NFPA Technical Committee on Air Conditioning (90A committee), the NFPA Fire Tests Committee and testing labs, because the definition of limited combustible is in the 90A standard and because testing labs and the Fire Tests committee have to deal with testing issues. The Panel is aware that several testing laboratories are listing limited combustible cables and that at least two companies offer listed limited combustible cable for sale. See comment 16-101 for test data comparing limited combustible versus conventional plenum cable.

Limited combustible cable is available as an option. Limited combustible cable is significantly better than conventional plenum cable. Inclusion of limited combustible cable correlates with NFPA 90A. Consistency between NFPA codes is beneficial. It is in the interest of fire safety to include limited combustible cable in the Code.

Note: "See Technical Correlating Committee action on Comment 16-98."

SUBMITTER: Jeffrey S. Deckman, SyNet Inc.
COMMENT ON PROPOSAL NO: 16-89
RECOMMENDATION: SyNet recommends that Code Panel 16 continue to accept this proposal.
SUBSTANTIATION: SyNet supports the acceptance and use of limited combustible cable. The NFPRF research project demonstrated that cable can be tested and listed for full compliance to the NFPA 255 and 259 test methods. Limited combustible cable is consistent with the full requirements of NFPA 90A and its originally intended fire safety performance. We believe this cable design would provide a significant improvement in fire safety and protect lives and property.

16- 101 - (725-71(b), 760-71 (b) (new), 770-51 (b), 800-51 (h), 820-51 (b) (New)): Accept

SUBMITTER: Andrew A. Bushelman, Avaya
COMMENT ON PROPOSAL NO: 16-89, 16-149, 16-169, 16-232, & 16-302
RECOMMENDATION: Continue to accept the proposals establishing limited combustible cable.
SUBSTANTIATION: Avaya supports the introduction of limited combustible cable because limited combustible cables exhibit significantly less smoke production than conventional combustible plenum cables. Avaya has an Underwriters Laboratories listing for limited combustible cable. The superior fire protection performance of the limited combustible versus a conventional combustible plenum cable is shown in the table below.

UL 910/NFPA 262 Test Parameters	Combustible Plenum Cable (CMP)	Limited Combustible Plenum Cable (CMP-50)
Peak Flame Spread range	0.5 – 2.0 feet	0.5
Average Optical Density range	0.10 – 0.13	0.05 – 0.07
Peak Optical Density range	0.27 – 0.34	0.1

Both cables consist of a 4-pair, 24 AWG FEP (fluorinated ethylene propylene)insulated core and thermoplastic jacket. The constructions are UTP (unshielded, twisted pair) with a nominal outside diameter of 0.22 inches. The combustible plenum cable has a low smoke PVC jacket and the limited combustible cable has a FEP jacket.
PANEL ACTION: Accept.

16- 102 - (725-71(b), 760-71 (b), 770-51(b), 800-51(h), 820-51(b) (New)): Accept

SUBMITTER: James R. Hoover, DuPont
COMMENT ON PROPOSAL NO: 16-89, 16-149, 16-169, 16-232, & 16-302
RECOMMENDATION: Dupont recommends that the National Electrical Code Panel 16 continue to accept the proposals establishing the limited combustible (-50) cable "option".
SUBSTANTIATION: DuPont supports introduction of limited combustible (-50) cable because it will correlate the National Electrical Code requirements for plenum cable with the basic requirement for material (including cables) in ceiling cavity plenums and raised floor plenums now in NFPA 90A sections 2-3.10.2(a) and 2-3.10.6(a).

Overall, the introduction of the limited combustible (-50) cable "option" is broadly beneficial to everyone because it recognizes that:

1. Limited combustible cables represent a significant improvement in fire safety.
2. Authorities Having Jurisdiction (AHJs) and end users have already requested it.
3. UL is now providing Limited Combustible cable listings based on AHJ requests.
4. Several cable companies have announced commercial availability of UL Listed limited combustible (CMP-50) cable products.
5. AHJs, building owners, and end users will have the option to specify higher fire performance products for special HIGH-RISK, HIGH-HAZARD, high-concentration cable situations where fire load, smoke load, life safety, electronic damage, function continuity, mission completion, and business outage are unresolved concerns.
6. Overall, competition and innovation are increased. The proposals provide "additional options", not "exclusive requirements".

All existing materials and products are still allowed. New, higher performance, safer, cheaper, thinner, lighter, eco-friendly, re-usable cable materials and cable products are emerging.

7. NFPA's National Fire Protection Research Foundation (NFPRF) research also now provides data to support these proposals. The initial NFPRF Limited Combustible Project work is complete and published in an Interim Report (copies available to Code Panel Members upon request). The report validates the use of the NFPA 255 Tunnel Test and the NFPA 259 Oxygen Bomb test standards for cables utilizing procedures already published in the existing standards. The results were quite good when compared to previous ASTM ISR Round Robin work utilizing the Steiner Tunnel.
8. The Oxygen Bomb was found to work very well to test either cables or cable components. Counter to recent claims, The Cone Calorimeter "won't and can't" measure the potential heat (i.e. gross heat of combustion) required to meet the primary requirements on NFPA 90A. Due to limitations in its design, test methods and operating limits, the Cone Calorimeter has been unable to assess the FULL potential thermal hazard of many (complex composite) datacom plenum cable constructions used today. Please see more details in the National Fire Protection Research Foundation "Fire Risk and Hazard Assessment Symposium" Proceedings, June 26-28, 1996, "Wire and Cable Combustion Efficiency Determinations Using Cone Calorimetry and the Oxygen Bomb", J. Hoover et al.
9. The Cone Calorimeter was also recently found to have major repeatability problems and difficulties in predicting fire hazards (i.e., measuring key heat release related combustion parameters) observed in real-scale cable tests according to a recently published UK Government Research Programme based on US and UK sourced commercial plenum cables, conducted by the DETR and entitled, "Study of Cable Insulation Fires in Hidden Voids", P. Fardell et al, copyright BRE and DETR May 2000. This work and the preceding companion PEP and PIT studies are the only recent large scale datacom plenum cable studies involving the Steiner Tunnel and Cone Calorimeter with direct BRE real-scale validation. Oxygen Bomb data was subsequently found to relate well to hazard characterization and real-scale fire experience. Scatter in the published Cone Calorimeter data made it of questionable value for any reliable fire performance predictions or fire hazard assessments.
10. The NFPRF Limited Combustible Project Report also provides validating data that indicates that conventional CMP rated combustible Exception cables can generate up to 1700% more smoke and 200-300% higher polymer fuel load than the primary requirements of NFPA 90A allow. The CMP-50 rated Limited Combustible cables tested can meet ALL of the much more extensive NFPA 90A primary requirements. AHJs and end users have already begun requesting these cables for use in certain HIGH-RISK, HIGH-HAZARD installations to protect life, property and critical functions (i.e., national defense, emergency services, finance and banking, air traffic control, fossil and atomic energy, telecom exchange, stock exchange, critical business operations, etc.).
11. Data from the NFPRF Limited Combustible Report and cable manufacturers can now help provide inputs for fire safety engineering based assessments to show that the much higher fire performance limited combustible (-50) cables can make significant contributions to reducing the hazards and risks associated with fires involving cables as large fire loads, fire paths, or fire sources, etc.

12. Real-scale evaluations of certain US sourced commercial combustible CMP Listed plenum cables (presented at the December 1998 NFPA 90A meeting) indicated these listed cables can cause significant flame spread and fire growth. Therefore, higher performance limited combustible (-50) cable "options" are needed for certain HIGH-RISK and HIGH-HAZARD installation situations. The proposed "correlation" of the NEC with the existing primary requirements of NFPA 90A will fulfill these existing fire safety needs.

13. Finally, various reports and charts have been circulating recently purporting to illustrate NFPA Fire Statistics involving plenum cables and plenum spaces. There are no NFPA "Plenum" Fire Statistics per se. The terms "plenum" and "plenum cable" do not exist in the NFPA data base. Upon inquiry to this point, NFPA personnel replied: "Your understanding that we do not have incident data coded as plenum fires is correct. What has been circulating, we believe, is data that has been relabeled … We do not assume that all or even most of these two areas of (fire) origin are plenums, and did not use the word "plenum" in the tables." (copies of this NFPA letter are available to Code Panel Members upon request).

Note: "See Technical Correlating Committee action on Comment 16-98."
SUBMITTER: George Thorning, Yale University
COMMENT ON PROPOSAL NO: 16-89
RECOMMENDATION: Yale recommends that Code Making Panel 16 continue to accept this proposal.
SUBSTANTIATION: We believe this cable design would provide a significant improvement in fire safety and protect lives and property. Yale supports the NFPA's acceptance and recognition of limited combustible cable in the 2002 NEC. The NFPRF research project demonstrates that cable can be tested and listed for full compliance to the NFPA 255 and 259 test methods. Limited combustible cable is consistent with the full requirements of NFPA 90A and its originally intended fire safety performance.

SUBMITTER: John Moseley, Suddath Van Lines, Inc.
COMMENT ON PROPOSAL NO: 16-89
RECOMMENDATION: Suddath Van Lines, Inc. recommends that Code Making Panel 16 continue to accept this proposal.
SUBSTANTIATION: Suddath Van Lines, Inc. advocates the endorsement and application of limited combustible cable. This cable design supplies a major upgrade in fire safety offerings. Cable can be tested and listed for full compliance to the NFPA 255 and 259 protocols; the NFPRF has already established this information. Limited combustible cable observes and applies the current guidelines of NFPA 90A, without the exception, and its fire safety performance tenet.

(Log #1586)

16- 107 - (725-71(b)): Reject
Note: "See Technical Correlating Committee action on Comment 16-98."
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-89
RECOMMENDATION: Delete proposed section 725-71(b) and associated notes.
SUBSTANTIATION: The introduction of a new class of cable ("Limited Combustible Cable") is premature at this time for the following reasons:

A. The note to the definition section 725.71(B), FPN No. 1 references NFPA 90A, Standard for the Installation of Air-Conditioning and Ventilating Systems for the definition of limited combustible. That definition is as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141J/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

a. Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50;

b. Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be combustible."

This definition was established and is applied to building construction materials and not to specific wiring methods or technologies for use in buildings. NFPA 255 and NFPA 259 were never intended for the evaluation of multi-component systems such as electrical and optical cable. More current test methods (other than NFPA 255 and 259), such as NFPA 262, the cone calorimeter, etc. provide reproducible smoke obscuration, flame spread, or heat release (not heat value) information and are more appropriate for measuring the fire hazards of cable. Not all parts of this "Limited Combustible" definition have been applied to the broad scope of cables. Until this definition can be shown as appropriate for cables (attainable and reproducible) it should not be deemed credible and supported by the National Electrical Code at this time. Referencing this inappropriate definition in the National Electrical Code is misleading and bad code.

B. The note references NFPA 255 as the test standard for smoke developed index. This test is not an appropriate test for cables for the following reasons:

a. NFPA 255 has not been harmonized, as has NFPA 262. NFPA 262 has a proven record, unlike NFPA 255.

b. NFPA 255 is not reproducible, whereas NFPA 262 has been shown to be reproducible. This lack of reproducibility has been demonstrated numerous times in round-robin testing of building materials among multiple labs.

The most recent example of this reproducibility problem has been demonstrated in the Interim Report of the Fire Protection Research Foundation (FPRF) "Limited Combustible Cable" (ex. "Permanent Plenum Cable") project, dated June 2000. This report states "The flame spread and smoke measurements in NFPA 255 show good repeatability but relatively poor reproducibility, i.e., the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error." (Page 9, section 4.1.2). In this case, with only two laboratories participating, errors in reproducibility were in the range of 100 percent. Given that numerous fire-testing tunnels exist, the range of error can be expected to be even larger.

This test is inappropriate for cables as the cables are installed against the top of the tunnel. This orientation is not similar to normal cable installations, and cable placement on top of the wire mesh is random in the tunnel.

C. Cable installed above ceilings does not become involved in the fire until near or at flashover. At that point in the fire development, the ceiling tile is falling to expose the cable. Cables in walls or below floors are generally exposed to the fire conditions even later in the fire development. These cables do not spread flame more than 5 ft when tested in accordance with NFPA 262. The proposed restrictions on cable appear excessive based on the fire record.

D. There is not a need established (fire record or hazard analysis) for a new cable category. There are two research projects that are intended to provide information on the fire hazard of cables. The ASHRAE project has not yet begun. This ASHRAE Project is being conducted by the National Research Council of Canada and is a broad based fire hazard assessment program developed to evaluate the hazard presented by the accumulation of plenum cables. This question has not yet been answered and developing cable categories to address a hazard that has not yet been defined is premature. The project when completed will assist in developing appropriate language for NFPA 90A and/or the National Electrical Code.

The FPRF project has only issued an interim report dated June 2000. This project has only accomplished a cursory review of one cable type in NFPA 255 and NFPA 259 and has just begun the experimental work on broader aspects of the "limited combustible" definition.

The proposals for the National Electrical Code that have been accepted by Code Making Panel 16 for the removal of all abandoned cable broadly addresses this problem now. The adoption of these proposals for removing all abandoned cable will significantly reduce the fuel load created by excessive cable accumulation.

E. The International Mechanical Code (IMC), the Uniform Mechanical Code (UMC), and the NFPA 90A (the membership and the NFPA Standards Council) have each recently rejected similar provisions to the ones being proposed for the National Electrical Code. These proposals for "limited combustible cables" have been rejected for several reasons including:

a. They will present confusion in the field;

b. They are not good code based on sound engineering principles;

c. They are not based on good fire hazard assessment information; and

d. Questions regarding the appropriateness and accuracy of the test protocols NFPA 255 and NFPA 259.

16- 112 - (725-71(b), FPN No. 2): Accept in Principle
Note: "See Technical Correlating Committee action on Comment 16-98."
SUBMITTER: Frederic B. Clarke, Benjamin Clarke Assoc., Inc.
COMMENT ON PROPOSAL NO: 16-89
RECOMMENDATION: Revise proposed FPN No. 2 to read:
FPN No. 2: For ~~further~~ information on the requirements for materials in ceiling cavity and raised floor plenums, see NFPA 90A-1999, Standard for the Installation of Air Conditioning and Ventilating Systems, Sections 2-3.10.1 Ceiling Cavity Plenum and 2-3.10.5 Raised Floor Plenum. Types CL2P and CL3P cables meet the basic requirements of this Section for materials for plenum use as well as those of Exception No. 1.
SUBSTANTIATION: The existing FPNs provide no information on material requirements in NFPA 90A-1999, so the word "further" is unnecessary.
The new text proposed in this comment distinguishes between materials allowable under the exceptions to Section 2-3.10.1 and 2-3.10.5 and those for general plenum use. This provides information for adopting jurisdictions, many of which do not now reference NFPA 90A and so may not otherwise recognize the distinction - and the potential difference in protection which it may provide.
PANEL ACTION: Accept in Principle.
Revise the text of the comment to read:
"Types CL2P-50 and CL3P-50 cables meet the basic requirements of this section for materials for plenum use as well as those of Exception No. 1."
PANEL STATEMENT: The revised text corrects an error in the comment.

16- 114 - (725-71(e)): Accept
SUBMITTER: Technical Correlating Committee National Electrical Code
COMMENT ON PROPOSAL NO: 16-91
RECOMMENDATION: The Technical Correlating Committee understands that the reference to "725-71(e)" in the Proposal is incorrect and should be "725-71(h)". The Technical Correlating Committee notes that this section will be renumbered "725-71(i)" based on the Action on Proposal 16-89. The Technical Correlating Committee directs that the action on this Proposal be revised to comply with the NEC Style Manual 3.1.4 regarding the use of an Exception within the same sentence as the main rule. The Technical Correlating Committee directs the Panel to refer to the action on similar Proposal 16-106 and correlate the wording of the two Proposals. A separate Exception may be appropriate. This action will be considered by the Panel as a Public Comment.
SUBSTANTIATION: This is a direction from the National Electrical Code Technical Correlating Committee in accordance with 3-4.2 and 3-4.3 of the Regulations Governing Committee Projects.
PANEL ACTION: Accept.
Revise the first sentence of 725-71(F) to read as follows:
"Type PLTC nonmetallic-sheathed, power-limited tray cable shall be listed as being suitable for cable trays and shall consist of a factory assembly of two or more insulated conductors under a nonmetallic jacket."
Revise 725-71(I) to read as follows:
"725.71(I) Markings. Cables shall be marked in accordance with 310.11 (A) (2),(3),(4),(5) and Table 725.71. Voltage ratings shall not be marked on the cables."
PANEL STATEMENT: The text has been revised to comply with the Manual of Style in accordance with the Technical Correlating Committee directive. The panel has modified 727-7 for correlation. Refer to panel action and statements on Comments 16-127 and 16-128.
(The panel notes that 725-71(e) is now 725.71(F) per the action of another proposal.)

16- 118 - (727-2(6)): Accept in Principle
SUBMITTER: David Wechsler, Union Carbide Corp.
COMMENT ON PROPOSAL NO: 16-97
RECOMMENDATION: Delete the word "control rooms" and revise the test as follows:
This has been corrected to 727-4(7)
(6) Under raised floors and in rack rooms where arranged to prevent damage to the cable.
SUBSTANTIATION: With due respect to the Panel, the term "control room" meaning a manned location has become a problem where authorities having jurisdiction have read the current text and infer that only in these "control rooms" that have raised floors and in rack rooms, can ITC be used. As the primary developer of this chapter, I can tell you that it was never the intent to restrict the installation in this limited sense. Rather the intent was to address the complete installation which included the area into which instrumentation cabling had to be run to be terminated from the field runs for its final purpose. In hindsight, perhaps the use of the term "control room" was a poor choice in words. The submitter concedes that by its very nature, ITC would not be suitable for just anywhere. However, in industrial applications, where the ITC ends up, may be called a "termination building room", or a "computer room or building" or a "control building". These areas utilize raised floors and we need to be able to complete the ITC runs to its end points at some DCS, computerized data collection, or instrumentation control point. While defining "control room" could be one solution, elimination of this term which is not defined within the NEC, provides a simple correction without compromising any aspect of the installation design safety.
PANEL ACTION: Accept in Principle.

(Log #633)

16- 119 - (727-4): Accept in Principle
SUBMITTER: James M. Daly, BICC General
COMMENT ON PROPOSAL NO: 16-98
RECOMMENDATION: The proposal should be accepted in part in principle.
Accept the proposal as written through (4).
Revise (5) as follows:
(5) As open wiring <u>without a metallic sheath or armor</u> between cable tray and equipment in lengths not to exceed 50 ft (15.24 m), where the cable is supported and protected against physical damage using mechanical protection, such as dedicated struts, angles, or channels. The cable shall be supported and secured at intervals not exceeding 6 ft (1.83 m).
Add (6) to read:
<u>(6) As open wiring between cable tray and equipment in lengths not to exceed 50 ft (15.24 m), where the cable complies with the crush and impact requirements of Type MC cable and is identified for such use. The cable shall be supported and secured at intervals not exceeding 6 ft (1.83 m)</u>.
Renumber the remaining list items as follows:
(7) As aerial cable on a messenger.
(8) Direct buried where identified for the use.
(9) Under raised floors in control rooms and rack rooms where arranged to prevent damage to the cable.
The SI units and inch-pound units in this proposal and comment should also be changed to agree with the panel action on Proposal 16-101.
SUBSTANTIATION: This modification will convert the exceptions into positive text and addresses the panel's concern that the original proposal did not include the installation requirements specified in Exception No. 2.
PANEL ACTION: Accept in Principle.
Revise the recommendation to read as follows:
The proposal should be accepted in principle.
Accept the proposal as written through (4).
Revise (5) as follows:
(5) As open wiring without a metallic sheath or armor between cable tray and equipment in lengths not to exceed 15 m (50 ft), where the cable is supported and protected against physical damage using mechanical protection, such as struts, angles, or channels. The cable shall be supported and secured at intervals not exceeding 1.8 m (6 ft).
Add (6) to read:
(6) As open wiring between cable tray and equipment in lengths not to exceed 15 m (50 ft), where the cable complies with the crush and impact requirements of Type MC cable and is identified for such use. The cable shall be supported and secured at intervals not exceeding 1.8 m (6 ft).
Renumber the remaining list items as follows:
(7) As aerial cable on a messenger.
(8) Direct buried where identified for the use.
(9) Under raised floors in rooms containing industrial process control equipment and rack rooms where arranged to prevent damage to the cable.
PANEL STATEMENT: The panel has corrected the metric values in accordance with the Style Manual and Proposal 16-101. Item 5 was changed to delete the word "dedicated" to correlate with Panel Action on Comments 16-120 and 121. Item 9 was also revised to correlate with the panel action on Comment 16-123.

16- 120 - (727-4 Exception No. 1): Accept in Principle
SUBMITTER: John E. Propst, Equilon Enterprises, LLC
COMMENT ON PROPOSAL NO: 16-99
RECOMMENDATION: The purpose for this comment is to support the following alternate proposal wording stated in Mr. Hughes' affirmative comment:

727-4 Exception No. 1 will read: Type ITC cable without a metallic sheath or armor shall be permitted to be installed as open wiring between cable tray and equipment in lengths not to exceed 50 ft (15.24 m), where the cable is supported and protected against physical damage using mechanical protection, such as ~~dedicated~~ struts, angles or channels. The cable shall be supported and secured at intervals not exceeding 6 ft (1.83 m).
SUBSTANTIATION: As a member of the original CMP 7 task force that drafted the original wording of 727, I do not believe that it was our intent to limit support incorporating struts to "dedicated" struts but rather to provide examples of methods that could be considered appropriate in providing protection against physical damage. With respect to the issue is protection, some segments of our industry such as offshore platforms and integrated process units have significant physical weight and space limitations. Through good engineering design structural and similar construction members can often provide physical protection as well as structural support for multiple systems. The deletion of the word "dedicated" would help clarify that the intent is to provide protection and not to overly prescribe how it is to be done.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to the panel action and statement on Comment 16-119.

(Log #1414)

16- 121 - (727-4 Exception No. 1): Accept in Principle
SUBMITTER: Kari Barrett, American Chemistry Council
COMMENT ON PROPOSAL NO: 16-99
RECOMMENDATION: 727-4 Exception No. 1 will read:

Type ITC cable without a metallic sheath or armor shall be permitted to be installed as open wiring between cable tray and equipment in lengths not to exceed 50 ft. (15.24 m), where the cable is supported and protected against physical damage using mechanical protection, such as ~~dedicated~~ struts, angels or channels. The cable shall be supported and secured at intervals not exceeding 6 ft (1.83 m).
SUBSTANTIATION: I am the person who proposed Proposal 16-99. Due to copy/paste error on my part, the proposed text and substantiation obviously does not apply to 727-4 Exception 1. The wording in this comment was my intent with the proposal. My substantiation is as follows:

The examples cited for mechanical protection could already be part of the building or equipment infrastructure, and if so, are not solely dedicated for the purpose of protection of a wiring system. This change will clarify the exception, avoid the interpretation that the mechanical protection means can only be used for that purpose, and continue to provide protection of the wiring system as intended.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to the panel action and statement on Comment 16-119.

(Log #868)

16- 122 - (727-4(4)): Reject
SUBMITTER: Frank H. Rocchio, The Okonite Co., Inc.
COMMENT ON PROPOSAL NO: 16-9
RECOMMENDATION: This proposal is for the removal of open wiring from 727-4(4) along with Exceptions No. 1 and No. 2 until such time as a test protocol exists where the cable tested must pass 100 percent of the impact tests performed.

Using a similar protocol for Type TC cable where only eleven feet of cable is tested and must pass 8 out of 10 impact tests at 1 ft intervals. This eleven ft of cable tested justifies the cable being permitted to go out of the tray for up to 50 ft. It would seem that any crush or impact failures in an unarmored cable should disallow the cable from leaving the tray.
SUBSTANTIATION: There is no test protocol for the testing of Type ITC open wiring. This type cable requires an uninsulated drain to be in contact with the Polyester - Aluminum tape shielded construction for pairs, triads, quads and other units. This uninsulated drain will not permit a Type ITC cable to pass a impact test. As such, the designation "open wiring" should not be permitted and the cable should not be permitted to leave the tray without overall armor for any distance.
PANEL ACTION: Reject.
PANEL STATEMENT: The submitter has made no specific recommendation.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21

(Log #604)

16- 123 - (727-4(7)): Accept
SUBMITTER: John E. Propst, Equilon Enterprises, LLC
COMMENT ON PROPOSAL NO: 16-97
RECOMMENDATION: The purpose for this comment is to support the original proposal and to reject the action of the panel. Note that Proposal 16-97 incorrectly referenced Section 727-2(6) and should have referenced 727-4(7) as noted in the panel comment. I would like to suggest that the panel consider accepting this proposal in principle and reword 727-4(7) to read:

727-4(7). Under raised floors in ~~control~~ rooms containing industrial process control equipment and rack rooms where arranged to prevent damage to the cable.
SUBSTANTIATION: As Mr. Wechsler points out, there is confusion in the industry related to the interpretation of "control room". The panel is not quite correct in stating that it was never the intent to allow ITC cable under a raised floor anywhere in a building. Along with Mr. Wechsler and several other people, I was also a member of the original CMP 7 task group that drafted the ITC section. At that time it was our intent to allow the use of ITC cable under all raised floors in industrial buildings that housed equipment related to the industrial control. Within our company, these are typically large integrated buildings designed specifically for the remote operation of multiple process units. The buildings typically contain the "control rooms, rack rooms, and a variety of additional rooms for housing process, computers, process controllers, process training simulators, and similar process related equipment. This equipment is typically all installed on raised floors and connected with ITC cables. Since there is not a clear definition of "control room," industry could deal with this issue by calling the entire facility the "control room," but it would help industry clarify this issue by eliminating the reference to "control room" in this section.
PANEL ACTION: Accept.

(Log #1429)

16- 124 - (727-4(7)): Accept in Principle
SUBMITTER: Kari Barrett, American Chemistry Council
COMMENT ON PROPOSAL NO: 16-97
RECOMMENDATION: Delete the term "Control Rooms".
SUBSTANTIATION: The application of type ITC is already limited to industrial establishments where the conditions of maintenance and supervision ensure that only qualified persons will service the installation (727-4). The notion that deleting the term "control room" will result in abuse of the intent of this section is not valid. Since "Control Room" is not a term used by all industrial users, deleting it will allow more consistent application of this section.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-123.

16- 126a - (727-7): Accept
SUBMITTER: CMP 16
COMMENT ON PROPOSAL NO: 16-106
RECOMMENDATION: Revise 727.7 to read as follows:
727.7 Marking. The cable shall be marked in accordance with Section 310.11(A)(2),(3),(4),and(5). Voltage ratings shall not be marked on the cable.
SUBSTANTIATION: Section 727.7 has been revised to comply with the Technical Correlating Committee directive of Comment 16-114. The minimum voltage rating for ITC is defined in UL-2250. The cable markings for ITC cable will be "the same marking requirements as other cables" under the jurisdiction of this code panel, with this change. The user will have the knowledge of the limitations of ITC because "Type ITC cable shall be permitted to be used in industrial establishments where the conditions of maintenance and supervision ensure that only qualified persons will service the installation."
PANEL ACTION: Accept.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:
AFFIRMATIVE: 21

(Log #596)

16- 127 - (727-7): Reject
SUBMITTER: John E. Propst, Equilon Enterprises, LLC
COMMENT ON PROPOSAL NO: 16-106
RECOMMENDATION: The purpose for this comment is to reject the action of the panel and to reject the original proposal.
SUBSTANTIATION: While the requirements of 727 limits the application of ITC cable to circuits operating at 150 volts or less, there is still a need to define the minimum voltage rating of the conductor insulation. From a historical perspective, in the development of ITC cable, it was necessary to define the cable's requirements within the NEC in order to provide guidance to UL in the development of UL 2250. At that time, it was felt that ITC should comply with the same marking requirements as other cables. The removal of the cable voltage rating would set an unsafe practice of allowing cables without voltage ratings to be applied in industrial applications where 600 volt rated and higher cables ae very common. Without a clearly identified voltage rating on the cable, it would require that the user have knowledge of the limitations stated in 727, and could be misapplied to higher voltage systems.
PANEL ACTION: Reject.
PANEL STATEMENT: Surface marking "300 V" on a cable that in application serves circuits operating at 150 volts or less could be confusing to the user and authority having jurisdiction. Refer to the FPN in Section 725-71(h) of the 1999 edition of the code. The submitter does not provide technical substantiation for his statement "the removal of the cable voltage rating would set an unsafe practice of allowing cable without voltage ratings to be applied ...". The suitability of the cables is determined by the application as specified in the code, not the voltage rating of the cable.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:
AFFIRMATIVE: 21

(Log #1412)

16- 128 - (727-7): Reject
SUBMITTER: Kari Barrett, American Chemistry Council
COMMENT ON PROPOSAL NO: 16-106
RECOMMENDATION: Delete entire proposal and return wording to the original text which reads: "The cable shall be marked in accordance with Section 310-11."
SUBSTANTIATION: It is not uncommon for a cable to have a maximum rated voltage marked on the cable and yet use the cable for lower voltages. For example, Article 725 Class I cables are rated at 600 volts and yet many applications using Class I cables are less than 600 volts. The submitter presents no documentation or fact finding evidence that having a maximum voltage printed on the cable has resulted in an unsafe condition. Further, Article 725 which defines Type PLTC (Power-limited Tray Cable), which is an identical twin of Type ITC, has been used for years with a surface marking requirement referencing Section 310.11(a) and with the same voltage constraints (See Chapter 9, Table 11(a) for example). Lastly, Section 727-4 provides that "Type ITC cable shall be permitted to be used in industrial establishments where the conditions of maintenance and supervision ensure that only qualified persons will service the installation." The ITC cable voltage marking would NOT confuse a "qualified" person.
PANEL ACTION: Reject.
PANEL STATEMENT: The panel agrees that there needs to be a specific reference to 310.11 but disagrees that all of 310.11 applies. Surface marking "300 V" on a cable that in application serves circuits operating at 150 volts or less could be confusing to the user and authority having jurisdiction. Refer to the FPN in 725-71(h) of the 1999 edition of the code. The submitter does not provide technical substantiation for his statement "the removal of the cable voltage rating would set an unsafe practice of allowing cable without voltage ratings to be applied ...". The suitability of the cables is determined by the application as specified in the code, not the voltage rating of the cable.
Refer also to panel action and statements on Comment 16-114 that removes the requirements for voltage marking on Type PLTC Cables.

ARTICLE 760 — FIRE ALARM SYSTEMS

(Log #299)

16- 129 - (760-2 Abandoned Cable (New)): Accept in Principle
SUBMITTER: Gerald Lee Dorna, Belden Wire & Cable Co.
COMMENT ON PROPOSAL NO: 16-109
RECOMMENDATION: The definition of "Abandoned Cable" should be the same here as what we accepted in Proposal 16-273. It should be:
"Cable that is neither terminated at ~~both ends, at a connector or other~~ equipment, not identified for future use with a tag."
This is the same wording we accepted for Proposal 16-273.
SUBSTANTIATION: The reason we took out the reference to connectors in Proposal 16-273 is because CATV cable usually has connectors attached. It was our concern that CATV cables would have connectors attached and then would not fall under the definition the panel had accepted in principal. If we make the definition the same as I have suggested above then it will make it irrelevant on whether the cable has connectors or not. I can foresee someone using the fact that the cable has a connector on it, therefore it does not fall under "abandoned cable" and does not need to be removed.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-131.

16- 130 - (760-2, Abandoned Cable): Accept in Principle in Part
SUBMITTER: Technical Correlating Committee on Signaling Systems for the Protection of Life and Property
COMMENT ON PROPOSAL NO: 16-109
RECOMMENDATION: Revise the proposed definition of abandoned cable to read as follows:
"Cable that is neither terminated at equipment, nor identified for future use with a dated tag."

SUBSTANTIATION: The definition proposed for 820-2 by the Panel Action of Proposal 16-273 is clear and concise and should be used consistently in all Articles. This proposed definition has been modified in the above recommendation to add the word "dated" before the word "tag." The tag should be dated so the authority having jurisdiction can determine the date on which the cable was designated for future use. This will establish a means to allow the decision of abandonment to be re-evaluated periodically if the authority having jurisdiction so desires.
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-131. Panel statement on Comment 16-246 includes the explanation for the rejected part.

16- 131 - (760-2): Accept in Principle
SUBMITTER: Robert W. Jensen, dbi-Telecommunications Infrastructure Design
COMMENT ON PROPOSAL NO: 16-109
RECOMMENDATION: New wording:
Abandoned Cable. Installed cable that is neither terminated at both ends at a connector or other equipment, nor identified for future use with a tag.
SUBSTANTIATION: BICSI added the word installed to show that the cable needs to be installed and not in the installers truck. We retained "terminated at both ends" because optical fiber cable is typically terminated at both ends when it is in use (i.e., when not abandoned). We removed the term "connectors" since the cable is typically connected directly to equipment.
PANEL ACTION: Accept in Principle.
Revise the recommendation to read as follows:
"Abandoned Fire Alarm Cable. Installed fire alarm cable that is not terminated at equipment other than a connector and not identified for future use with a tag."
PANEL STATEMENT: The revised text clearly expresses the intended definition, correlates with similar definitions in other articles and complies with the Manual of Style.

16- 135 - (760-3(a)): Accept in Principle
SUBMITTER: Stanley Kaufman, Lucent Technologies
COMMENT ON PROPOSAL NO: 16-144
RECOMMENDATION: Delete "not intended for future use."
SUBSTANTIATION: It is redundant to state "Abandoned cables not intended for future use...", since abandoned cables are defined as not being intended for future use.
PANEL ACTION: Accept in Principle.
Revise the second sentence of 760-3(a) in the panel action of Proposal 16-144 to read as follows:
The accessible portion of abandoned fire alarm cables shall not be permitted to remain.
PANEL STATEMENT: The intent is not to remove cables where it would be extremely difficult or damaging to the building or the remaining cables.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:
AFFIRMATIVE: 21

(Log #1580)

16- 136 - (760-3(a)): Accept in Principle in Part
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-144
RECOMMENDATION: Revise text to read as follows:
Spread of Fire or Products of Combustion. Installations in hollow spaces, vertical shafts, and ventilation or air-handling ducts shall be made so that the possible spread of fire or products of combustion will not be substantially increased. Openings around penetrations through fire resistance-rated walls, partitions, floors, or ceilings shall be firestopped using approved methods to maintain the fire resistance rating.
Abandoned cables not intended for future use shall not be permitted to remain.
FPN: Directories of electrical construction materials published by qualified testing laboratories contain many listing installation restrictions necessary to maintain the fire-resistive rating of assemblies where penetrations or openings are made.
SUBSTANTIATION: This definition under the section entitled "Spread of Fire or Products of Combustion" is not consistent throughout the Code. This comment uses language from ROP 16-250 [850-52(B)] to provide a consistent requirement throughout the code.
The same comment is being made for the following sections:
640-3A (ROP 16-1a)
645-5D6 (ROP 12-106)
725-3B (ROP 16-80)
770-3A (ROP 16-176)
820-3A (ROP 16-313)
820-52B (ROP 16-311)
8320-3A (ROP 16-364)
830-58B (ROP 16-368)
PANEL ACTION: Accept in Principle in Part.

PANEL STATEMENT: The panel accepts in principle the statement regarding abandoned cables. Refer to panel action on Comment 16-135. This satisfies the submitter's concerns.

The current reference to 300-21 satisfies the balance of the comment, which is rejected. That portion of the comment repeats the text of 300-21.

16- 139 - (760-5): Reject
SUBMITTER: Glenn W. Zieseniss, Crown Point, IN
COMMENT ON PROPOSAL NO: 16-112
RECOMMENDATION: Change the "Accept in Principle" to "Reject".
SUBSTANTIATION: I agree with Mr. Egesdal's and Mr. Speer's negative vote and comment on Proposal 16-192. This proposal is giving a "blanket okay for any type of ceiling tile to support the possible added weight of 3 cables of less than 1/2 in. in diameter on each ceiling tile. The proposal does not affirm that the ceiling tile industry was contacted of adding weight to lay on their product. This product is not part of the building structure, and is not designed to be suitable for supporting cables. I have seen ceiling tiles which look as if made of fiber glass insulation which has a finished surface on the exposed side of the ceiling. It is my belief that this ceiling tile would not accept additional weight upon it. I have contacted three ceiling tile companies or organizations on this proposal. They all suggested that their ceiling tiles are not to support additional weight. I have provided copies of my e-mail contacts.

NOTE: Supporting Material is available at NFPA Headquarters.
PANEL ACTION: Reject.
PANEL STATEMENT: The recommendation of Comment 16-137a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications cables in existing construction. The restrictions contained in Comment 16-137a limit both the number and size of wires and cables permitted on each ceiling panel, thereby controlling weight and accumulation so that cables can be easily moved aside to permit access. The submitter's concern about weight is addressed by decreasing the size of the cable to 1/4 inch and limiting the number of cables to three per each 10 ft x 10 ft area.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:

SPEER: See my explanation of negative vote on Comment 16-27a.

(Log #859)

16- 140 - (760-5): Accept in Principle in Part
SUBMITTER: Larry F. Miller, National Electrical Manufacturers Association (NEMA)
COMMENT ON PROPOSAL NO: 16-112
RECOMMENDATION: The Panel should continue to Accept the proposal in Principle but revise the Panel action text to read as follows:

760-5. Access to electrical Equipment Behind Panels Designed to Allow Access.

Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use <u>or maintenance.</u> Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.

b.<u>1. Installation of cables in suspended lay-in type ceiling spaces shall comply with 300.11.</u>

<u>2. Installation of cables in other than suspended lay-in type ceiling spaces shall comply with 300.11 where the space is accessible.</u>

<u>3.Where the ceiling is not the lay-in type, and the space is not accessible, three cables less than 13 mm (0.5 in.) shall be permitted to be installed unsupported by the building structure between access points or access panels.</u>

~~Buildings with existing cabling systems.~~

~~Where practicable, installation of cables shall comply with Section 300.11. Where impracticable to comply with Section 300.11, cables less than 13 mm (0.5 in) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.~~

~~1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.~~

~~2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum three supported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid."~~

SUBSTANTIATION: We agree with Mr. Egedsal's and Mr. Speer's negative comments that suspended ceilings are not intended to support electrical wires or cables.

Section 300-11(a)(1) (wiring located within the cavity of a fire-rated floor-ceiling or roof-ceiling) allows an exception for wiring that has been tested as part of the fire-rated assembly. This proposal could compromise the fire-rating of the ceiling by overriding that requirement. The words "or maintenance" have been added because so much of the damage occurs in ceiling spaces as various trades perform maintenance.

The submitter states that he has submitted companion proposals for Articles 725 760, 770, 820 and 830. If each of these articles will allow three cables per ceiling tile, this could result in a total of 18 cables per ceiling tile, which appears to be approaching the "excessive accumulation" the submitter agrees could be a hazard. Limiting the size and quantity of cable permitted to be fished in non-lay-in ceiling spaces will help control the weight of cable (combined with that permitted in the other articles referenced above) on these ceilings.
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: The panel rejects the recommended addition of the word "maintenance." The term "normal building use" includes "maintenance." The balance of the recommendation

is accepted in principle. Refer to the recommendation and substantiation on Comment 16-137a.

(Log #978)

16- 141 - (760-5): Accept in Part
SUBMITTER: Palmer Hickman, Royersford, PA
COMMENT ON PROPOSAL NO: 16-112
RECOMMENDATION: Reject Proposal 16-112 and retain present 760-5 as it appears in the 1999 NEC.
SUBSTANTIATION: I would strongly urge Code-Making Panel 16 to reconsider their action on this proposal. The proposed 725.5(B)(2) would now permit three cables to be installed on the tile of a suspended ceiling, without providing any technical substantiation for this allowance.

I offer the following reasons against accepting this proposal.

1) Chapters 1-4 apply except as amended by Chapters 5, 6, and 7. Sections 300-11(a)(1) and (2) state wiring shall not be supported by ceiling assembly.

2) Section 725-5 deals with access to electrical equipment, not support of wiring

3) Code-Making Panel 3 reaffirmed their prohibition of ceiling assemblies being used beyond the manufacturers design parameters in the Panel Statement to Comments 3-53 and 3-57 of the 1998 ROC, and Proposal 3-68 of the 2001 ROP. In the later reference, Code-Making Panel 3 states: "The panel reaffirms its position that an independent means of support shall be provided for all wiring, not just branch circuit wiring...".

I understand that this proposed allowance of ceiling support only applies to buildings with existing cabling systems where it is "impracticable" to comply with 300-11. Impracticability does not provide technical substantiation to allow a ceiling assembly that has not been evaluated to support the potential additional load of three cables on each and every ceiling tile. Essentially, the ceiling assembly is expected to carry the additional load of potentially hundreds of cables installed directly on it. As an example, a 100 ft X 100 ft room with a suspended ceiling using 2 ft x 2 ft tiles, would be expected to carry the full weight of 150 cables.

The substantiation offered by the submitter of this proposal does not even support the proposed change. He claims that "a limited amount of wiring or cabling laid directly on a suspended ceiling is permitted..." without stating where this permission is given, and by whom. The entire substantiation of the submitter seems contrary to the action of the panel. He begins his substantiation by stating "Section 725-5 may be misinterpreted to mean that conductors and cables may not be placed directly on suspended ceiling." He notes that the 1999 NEC Handbook "Figures 725-2 and 725-3 lead the reader to conclude that no wires or cables are permitted to rest directly on the suspended ceiling." The submitter also stated Code-Making Panel 16 responded to a proposal to Article 725 (1992 TCD Comment 16-18) that the proposed requirement "...would still allow some cabling of a limited quantity above the ceiling tile, but not an excessive amount." Note the words "above the ceiling tile", not on the ceiling tile. I feel these examples are not misinterpretations, but rather correct interpretations, and substantiation to reject this proposal.

In conclusion, I respectfully disagree with the Panel Action on this Proposal. I feel the implications are quite serious. I find no technical substantiation to warrant such a dramatic change. The substantiation of the submitter does not appear to support this change, but rather the rejection of it.
PANEL ACTION: Accept in Part.
The panel accepts the portion of the comment to retain Section 760.5, and rejects the portion of the comment to reject Proposal 16-112.
PANEL STATEMENT: Refer to the recommendation and substantiation on Comment 16-137a. Also refer to the panel action and statement on Comment 16-139.

16- 142 - (760-5): Accept in Principle
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-112
RECOMMENDATION: Revise as follows:

760-5. Access to Electrical Equipment Behind Panels Designed to Allow Access. Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.

b. Buildings with existing cabling systems. Where practicable, installation of cables shall comply with Section 300-11. Where impracticable to comply with Section 300-11, cables less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.

1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.

2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum <u>of</u> three unsupported cables on top of ~~any one~~ <u>each</u> ceiling tile, <u>i.e., up to three wires and cables are permitted to lay on a ceiling tile.</u> The cables shall be run parallel to the ceiling grid.

SUBSTANTIATION: Proposed Section 760-5(b)(2), as presently written in Proposal 16-112, panel action, is confusing and could be interpreted as permitting a total of only three unsupported wires and cables above a suspended ceiling. The intent of the panel was that up to a maximum of three unsupported wires and cables may be routed across each and every ceiling tile. The revision proposed in this comment clarifies and accomplishes the intent of the panel. This is a companion comment and is intended to correlate with comments on Proposals 16-38, 16-159, 16-192, 16-276, and 16-332.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to the recommendation and substantiation on Comment 16-137a.

(Log #1164)

16- 143 - (760-5): Accept in Principle
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-112
RECOMMENDATION: Revise as follows:

760-5. Access to Electrical Equipment Behind Panels Designed to Allow Access. Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.

b. Buildings with existing cabling systems. ~~Where practicable, installation of cables shall comply with Section 300-11. Where impracticable to comply with Section 300-11,~~Cables less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.

1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.

2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.

<u>Where the maximum number of cables permitted in 1 or 2 will be exceeded, installation of cables shall comply with Section 300.11.</u>

SUBSTANTIATION: The Technical Correlating Committee has directed that Proposal 16-112 be revised to comply with the NEC Style Manual 3.2.1 relative to the use of unenforceable terms. The proposed revision contained in this comment removes the unenforceable terms "practicable" and "impracticable"; the remaining text is in agreement with the NEC Style Manual 3.1.2 using the phrase "shall be permitted" to indicate allowed optional

or alternate methods. The added text (final sentence) provides direction on how to proceed if the limits of 760-5(b)(1) or (2) will be exceeded. This is a companion comment and is intended to correlate with comments on Proposals 16-38, 16-159, 16-192, 16-276, and 16-332.
PANEL ACTION: Accept in Principle.

16- 144 - (760-5): Accept in Principle
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-112
RECOMMENDATION: Continue to accept in principle.
SUBSTANTIATION: Panel 16 should continue to accept this proposal in principle as it provides a reasonable and safe solution to placing a limited number of signaling and communications wires and cables in existing construction. The restrictions contained in the proposed change limit both the number and size of wires and cables permitted on each suspended ceiling panel. In this manner additional weight, as well as an accumulation of wires and cables that would otherwise restrict access above suspended ceiling panels, is controlled and limited. The limited number of cables permitted can easily be moved aside to permit access. Some concern has also been expressed that cables placed directly on the ceiling panels would degrade the fire rating of the ceiling. The suspended ceiling, part of a membrane that is intended to retard fire from spreading into the ceiling cavity, would be unaffected in its ability to retard the spread of fire by a limited number of wires and cables resting on top of the panels. This is a companion comment and is intended to correlate with comments on Proposals 16-38, 16-159, 16-192, 16-276, and 16-332.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to the substantiation on Comment 16-137. This action meets the intent of the submitter.

16- 137a - (760-5, 6, 7, 8, 9): Accept
Note: The Technical Correlating Committee directs that the references to Articles 640 and 650 be deleted because the panel did not accept similar requirements in those articles. The Technical Correlating Committee also directs that the FPN which contains a mandatory requirement be deleted to comply with the NEC Style Manual.
SUBMITTER: CMP 16
COMMENT ON PROPOSAL NO: 16-112
RECOMMENDATION: Renumber current Section 760-6 as 760-9.
Renumber current Section 760-7 as 760-11.
Renumber current Section 760-8 as 760-6.
Retain the existing 1999 code text for Section 760-5 (unmodified).
Add new Section 760.7 to read as follows:
760.7 Installation of Circuits.
Non-power-limited fire alarm and power-limited fire alarm circuits shall be installed in compliance with A or B.
A. New Ceiling Construction. The installation of cables in new ceiling construction shall comply with Section 300-11.
B. Existing Ceilings.
1. Fire-Rated Ceilings. The installation of cables in the cavity of an existing fire-rated ceiling assembly shall comply with Section 300-11.
2. Non-Fire-Rated Ceilings. For installations in the cavity of an existing non-fire-rated ceiling assembly, cables less than 6 mm (0.25 in) in diameter shall be permitted to be installed unsupported from the building structure in accordance with the following:
a. Fixed or Hard Ceilings. In areas having fixed or hard ceilings with access points or access panels, a combined total of three cables from Articles 640, 650, 725, 760, 770, 800, 820 and 830, shall be permitted to be placed between access points or access panels in the ceiling. Additional cables shall be installed in accordance with 300.11.
b. Suspended Lay-In Ceilings. In areas having suspended lay-in ceilings, in any 3 m by 3m (10 ft. x 10 ft) ceiling area, a combined total of three cables from Articles 640, 650, 725, 760, 770, 800, 820 and 830, shall be permitted to be installed directly on the ceiling grid. Additional cables shall be installed in accordance with 300.11.
FPN. Cables of all types are included in the total limit of three cables, not three cables from each article.
SUBSTANTIATION: Proposal 16-112 was accepted in principle to permit the installation of unsupported cables under limited conditions. Proposal 16-112 text, however, was too broad and unclear. The text of this comment clarifies the original intent. The new text includes requirements to comply with 300.11. Permitted installation conditions will not compromise the integrity of fire-rated ceilings. For non-fire-rated ceilings, the permitted relief from Section 300.11 is limited to very specific conditions. Section 760.5 is not being modified because the accessibility requirements should remain.
The sections have been renumbered so that they appear in a logical order.
PANEL ACTION: Accept.

CAUDILL: The Society of the Plastics Industries could not reach a consensus position on this issue.

(Log #741)

16- 147 - (760-5(b)): Accept in Principle in Part
SUBMITTER: Richard P. Owen, City of St. Paul, Electrical Inspection
COMMENT ON PROPOSAL NO: 16-112
RECOMMENDATION: Replace (b) of the proposal with the following text:

(b) Buildings not Covered Under (a) Above. In areas having ceilings with access points or panels and having 900 mm (3 ft) or less vertical clearance above the ceiling, it shall be permissible to fish a maximum of 3 cables, each less than 13 mm (0.5 in.) in diameter, between access points in the ceiling.

SUBSTANTIATION: The Technical Correlating Committee directed Panel 3 Chair Raymond Weber to form a Task Group to review these proposals and to submit the results as comments to Panel 16. Task Group 3-16, consisting of Chair Weber, members Steven Speer; Lee Hewitt; Richard Owen and Ron Maassen held a conference call on October 3, 2000 and developed the above language as a comment. The Task Group was concerned with allowing unsupported cabling above suspended ceilings, since companion proposals for Articles 725, 760, 770, 800, 820 and 830 would also allow this limited cabling without support. The possible accumulation of cable allowed by all these articles would be excessive and would both limit access to a ceiling and conflict with Section 300.11. Rewording of (b) also eliminated the unenforceable terms "practicable" and "impracticable" as directed by the Technical Correlating Committee.
PANEL ACTION: Accept in Principle in Part.

The panel rejects the specific limitations in the comment but accepts the principle of permitting a limited number of cables.
PANEL STATEMENT: The recommendation of Comment 16-137a provides a reasonable, safe, and practical solution to placing a limited number of unsupported fire alarm cables in existing construction.

(Log #1255)

16- 148 - (760-5(b)(2)): Reject
SUBMITTER: J. Paul Spinn, USG Research & Technology Center
COMMENT ON PROPOSAL NO: 16-112
RECOMMENDATION: Delete the following text:

In areas having suspended lay in ceiling, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.

SUBSTANTIATION: By allowing a maximum of three unsupported cables on top of any one (or more) ceiling tiles, the fire-rating of the assembly and the Class A surface burning characteristic requirement, which includes flame spread and smoke development, could be jeopardized. By decreasing the fire-rating of the plenum assembly and the surface burning characteristic of the ceiling tile, the life safety of the occupants can be negatively affected. By rejecting this proposal, these problems can be eliminated.

To substantiate the comment made for the proposal, four key points are provided:

[1] For a fire rated floor/ceiling or roof/ceiling assembly, placement of unsupported cables on top of any one ceiling tile or a row of ceiling tiles could invalidate the fire-rating for a particular assembly. The rationale for this argument are:
(a) The weight of the cables could cause premature tile fallout leading to an early failure of the assembly, which is tested in accordance with NFPA 251 or ASTM E 119.
(b) The increased heat of combustion associated with the cable jackets, which commonly use plastics, will add to the total fire load of an assembly. As the total fire load increases for an assembly, the fire endurance of the assembly will decrease, which could jeopardize an assembly's fire-rating.

[2] For a Class A ceiling, placement of unsupported cables on the ceiling can effect flame spread and smoke development performance and jeopardize the required Class A rating for the ceiling tiles. The rationale for this argument are:
(a) The flame spread will increase due to the increased total heat load, which is caused by the plastic on the cable jacket.
(b) The smoke development will increase due to the cable jackets, which are usually plastic such as PVC or CPVC.

[3] The placement of unsupported cables on top of any one or more ceiling tiles presents potential life safety issues for occupants due to the decreased fire-rating of the floor/ceiling or roof/ceiling or an increase in the ceiling surface burning characteristics.

[4] Placement of unsupported cables on top of any one ceiling tile or a row of ceiling tiles would increase ceiling tile sag due to increased weight of the cables on the ceiling tiles, and would impair the accessibility of the ceiling plenum.
PANEL ACTION: Reject.
PANEL STATEMENT: The recommendation of Comment 16-137a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications cables in existing construction. The restrictions contained in Comment 16-137a limit both the number and size of cables permitted on each ceiling panel, thereby controlling weight and accumulation so that cables can be easily moved aside to permit access. The submitter's concern about weight is addressed by decreasing the size of the cable to 1/4 inch and limiting the number of cables to three per each 10 ft x 10 ft area. The revised text precludes the installation of cables in all fire-rated ceiling assemblies.

SPEER: See my explanation of negative vote on Comment 16-27a.

(Log #2084)

16- 149 - (760-5(b)(2) (New)): Accept in Principle in Part
SUBMITTER: Marcelo M. Hirschler, GBH International
COMMENT ON PROPOSAL NO: 16-112
RECOMMENDATION: Revise text as follows:

760-5. Access to Electrical Equipment Behind Panels Designed to Allow Access

Access to equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).

a. New building construction (e.g. renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.

b. Buildings with existing cable systems. Where practicable, installation of cables shall comply with Section 300.11. Where impracticable to comply with Section 300.11, in those areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables less than 13 mm (0.5 in) in diameter, between access points in the ceiling. ~~cables less than 13 mm (0.5 in) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.~~

~~1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.~~

~~2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.~~

SUBSTANTIATION: The permission granted by the panel to install cables on suspended ceiling tiles should be rescinded. Neither cables nor any other item should be installed on top of a suspended ceiling tile. The support systems of suspended ceilings are not designed to resist any significant amount of weight without being deflected or broken.

This issue has been raised on Proposal 16-192 (log 1665) in negative comments by two panel members, Mr Egesdal and Mr Speer, who both correctly point out that suspended ceiling tiles are not intended to support the weight of electrical cables. Mr. Sandy Egesdal repeats his negative comment on this proposal.

The point made by the Technical Correlating Committee on proposal 16-38 that such use would constitute an exposed use of cables is an additional consideration to rejecting this part of the proposal.
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: The panel accepts the principle of permitting a limited number of cables to be installed in a fixed or hard ceiling. The panel rejects the balance of the submitter's recommendation including the limiting of the installation of cables in a suspended lay-in ceiling . The recommendation of Comment 16-137a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications cables in existing construction.

(Log #1156)

16- 150 - (760-8): Reject
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-115
RECOMMENDATION: Delete 760-8 and incorporate the information in 760-5 as follows:

760-5. ~~Access to Electrical Equipment Behind Panels Designed to Allow Access,~~ Mechanical Execution of Work. Fire alarm circuits shall be installed in a neat and workmanlike manner. Access to electrical equipment shall not be denied by an accumulation of ~~wires and~~ cables and conductors that prevents removal of panels, cables and conductors shall be installed in such a manner that ~~the cable~~ they will not be damaged by normal building use. ~~Access to electrical equipment behind ceilings designed to allow access~~ Cables and conductors installed exposed shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables and conductors shall comply with Section 300.11. Cables and conductors shall be supported by structural components of the building. Such cables and conductors shall be attached to structural components at intervals not exceeding 1.52 m (5 ft) and within 305 mm (12 in.) from every cabinet, box or fitting by straps, staples, hangers or similar fittings designed and installed so as not to damage the cable or conductors. The installation shall also conform with Section 300-4(d).

b. Buildings with existing cabling systems. Where practicable, installation of cables and conductors shall comply with ~~Section 300-11~~ 760-5(a). Where impracticable to comply with ~~Section 300-11~~ 760-5(a), cables less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.

1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.

2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.

SUBSTANTIATION: This is a companion comment and is intended to correlate with similar comments on Proposals 16-39, 16-159a, 16-192a, 16-276a, and 16-333a. Sections 760-5 and 760-8 actually address the same issue, the mechanical execution of work. Accessibility behind panels designed to allow access is really an "execution of work" issue. Additionally, the Technical Correlating Committee has identified a potential conflict between the panel action on Proposals 16-38 and 16-39, that would also result here in 760. This comment editorially combines 760-5 and 760-8 into a single Section 760-5 requiring attachment to the building structure of exposed cables and conductors and, where impracticable to do so, permits a limited number of cables and conductors of specified maximum size to be placed on suspended ceiling tiles. It accommodates the intent of both proposals that cables and conductors should be supported by the building structure, but in extenuating circumstances in existing construction, a limited number and weight of cables and conductors may be placed on a suspended ceiling.
PANEL ACTION: Reject.
PANEL STATEMENT: The sections should not be combined. Refer to the recommendation and substantiation for Comment 16-137a where these recommendations are addressed.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:

(Log #1430)

16- 151 - (760-8): Accept in Part
SUBMITTER: Kari Barrett, American Chemistry Council
COMMENT ON PROPOSAL NO: 16-115
RECOMMENDATION: Delete the following text:
~~Such cables shall be attached to structural components at intervals not exceeding 1.52 m (5 ft) and within 305 mm (12 In.) from every cabinet, box or fitting by straps, staples, hangers or similar fittings designed and installed so as not to damage the cable. The installation shall also conform with Section 300-4(d).~~
SUBSTANTIATION: The addition of this text would make the mandatory requirements of this section overly specific. The present wording is sufficient guidance to both the installer and the authority having jurisdiction.
PANEL ACTION: Accept in Part.
Revise the third sentence of the panel action text of Proposal 16-115 to read as follows:
"Such cables shall be attached to structural components by straps, staples, hangers or similar fittings designed and installed so as not to damage the cable."
PANEL STATEMENT: The panel accepts the removal of specific distances for the attachment of the cable. The panel does not agree that the existing code wording is sufficient guidance to both the installer and the authority having jurisdiction.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:
AFFIRMATIVE: 20
NEGATIVE: 1
EXPLANATION OF NEGATIVE:
SPEER: The inclusion of specific distances for spacing attachment points if not "overly specific" in its guidance offered to installers or the authority having jurisdiction. The specific distances mentioned, merely ensure that cables installed will be properly supported and, thus, protected from damage.

(Log #1639)

16- 152 - (760-8): Reject
SUBMITTER: Andy Scott, National Cable Television Association
COMMENT ON PROPOSAL NO: 16-115
RECOMMENDATION: Reject Proposal 16-115.
SUBSTANTIATION: NCTA, on behalf of the cable television industry, strongly urges Panel 16 to reject these proposals. While attachment every 5 ft may be a practice in many cases, it also may be overly restrictive and unnecessary in others. The requirement to support cables every 5 ft is outside the scope of the code. The NCTA urges Panel 16 not to allow the NEC to serve as an Installation Manual.
PANEL ACTION: Reject.
PANEL STATEMENT: The panel action on Comment 16-151 addresses the concerns in the submitter's substantiation.

(Log #887)

16- 154 - (760-52(c) (New)): Hold
SUBMITTER: Irving Mande, EST
COMMENT ON PROPOSAL NO: 16-132
RECOMMENDATION: Add a new subsection (c) to read as follows:

(c) PLFA and NPLFA Wiring Methods Used on the Same Power-limited Circuit. PLFA and NPLFA conductors and cables, as permitted by Exception No. 2 of (a) and by (b) above, shall be permitted to be used on different segments of the same power-limited circuit where installed in accordance with the requirements of 760-54.

SUBSTANTIATION: In a previous code cycle. CMP 16 approved Class 1 nonpower-limited conductors and cables to be used on

different segments of the same power-limited circuit with Class 2 and Class 3 power-limited conductors. Subsection (c) will allow the same rule to be applied to PLFA and NPLFA wiring.
PANEL ACTION: Hold.
PANEL STATEMENT: The panel is holding Comment 16-154 because it is new material and has not had public review.

(Log #442)

16- 155 - (760-54(c), Exception): Reject
SUBMITTER: Dan Leaf, Palmdale, CA
COMMENT ON PROPOSAL NO: 16-138
RECOMMENDATION: Accept in principle, revise exception.
Exception: Attachment to a service mast in accordance with Exception No. 2 for 800-10(b) shall be permitted.
SUBSTANTIATION: Section 760-7 covers circuits extending beyond buildings and refers to Part B of Article 800 and Article 225. Sections 800-10(b) and 225-19 have exceptions for termination (support) at a service mast. The present text prohibiting support by any conduit or raceway appears to be in conflict.
PANEL ACTION: Reject.
PANEL STATEMENT: The submitter correctly states that the requirements for circuits extending beyond buildings are in Articles 800 and 225. For that reason the proposed change is not appropriate for Article 760.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:
AFFIRMATIVE: 20
NEGATIVE: 1
EXPLANATION OF NEGATIVE:
TODD: The power service mast interface between NEC and NESC wiring does not need NEC ruling on attachments other than power conductors.
The submitter's comment is rejected for these reasons:
1. Panel 4 has continued to reject any attachments other than the power service conductors in article 230-28.
2. UL will not list this mast with unknowns of utility NESC span lengths, conductor loading levels (i.e., ice, wind, etc.) and multiple point sub-attachments, such as CATV and telephone service drop cables.
3. The electric utility industry has safety and subsequent liability concerns with power conductors on multiple attachment masts. This concern relates to the increased risk of snagging of the nonpower attachments and tearing down the power conductors.
This interface concern should be resolved between local power utility and telecommunication companies, not in the NEC. It is in the interest of fire and public safety to keep the power service mast for the exclusive safe environment of power conductors.

16- 156 - (760-54(e)): Accept in Principle
SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.
COMMENT ON PROPOSAL NO: 16-144
RECOMMENDATION: Continue accepting this proposal in principle, by retaining the phrase: "Abandoned cables, not intended for future use shall not be permitted to remain."
SUBSTANTIATION: There is a potential for increased fire hazard or fire risk when any cable, irrespective of whether it is or is not limited combustible, remains as fuel load unnecessarily once it has been taken out of use. Materials that are limited combustible can also burn (i.e., they are not noncombustible) and also increase the fire load. Furthermore, all abandoned cables can also affect the safety of plenums because of their weight. There is, thus, no justification for permitting any cable to remain in a plenum once it is abandoned and not intended for future use.
PANEL ACTION: Accept in Principle.

16- 165 - (Table 760-61): Reject
Note: "See Technical Correlating Committee action on Comment 16-98."
SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.
COMMENT ON PROPOSAL NO: 16-145
RECOMMENDATION: This proposal should be rejected, the references to CMP-50 and MPP-50 should be deleted from the Table 760-61 and not incorporated into Figure 760-61 and the CMP-50 and MPP-50 classifications should not be created.
SUBSTANTIATION: The CMP-50 and MPP-50 classifications are unnecessary classification because they are not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report,

Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}
* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}
* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.
* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."
* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $- C H_2 - + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2 H_3 Cl)_n + 2.5\ n\ O_2 = 2\ n\ CO_2 + n\ H_2O + n\ HCl$$

$$(C_2 H_3 Cl)_n + 2.75\ n\ O_2 = 2\ n\ CO_2 + 1.5\ n\ H_2O + 0.5\ n\ Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\ H_2O + 0.5\ N_2 + 1.25\ O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a H_b O_c F_e + (a+b/4-c/2-e/4)\ O_2 + (n+1/2)*e*(1-x) - b/2)\ H_2O = (a-ex/4)\ CO_2 + ex/4\ CF_4 + e(1-x)\ (HF) + e(1-x)\ n\ H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

16- 166 - (Table 760-61): Reject

SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.

COMMENT ON PROPOSAL NO: 1-145

RECOMMENDATION: Delete reference to CMP-50, MMP-50, and FPLP-50 cables in Table 760-61 and Figure 760-61.

SUBSTANTIATION: The new cable classification "Limited Combustible Cable" if deleted as recommended by comments to sections 725.71(b) [16-89]; 760-71(e) [16-149]; 770-51(b) [16-169]; 800-51(h) [16-232]; and 820-51(b) [16-302] will not be included in the Code. This type cable designation is not needed and is premature - see related comments for complete substantiation.

PANEL ACTION: Reject.

SUBMITTER: Irving Mande, Edwards Systems Technology (EST)
COMMENT ON PROPOSAL NO: 16-147
RECOMMENDATION: Accept this Proposal after making the following revisions:
In Figure 760-61, delete all entries in "Coaxial Cables" column and the horizontal arrows directed toward the FPL type cables. Also revise the header for FPL column only, to read: "Multiconductor and Coaxial cables". Below the Figure, delete the line that reads Type MP-Multipurpose cables (coaxial cables only).
In Table 760-61, delete all of the "Coaxial" column under "Permitted Substitutions". Add "and Coaxial (FPL type cables only)" to the heading of the "Multiconductor" column.
SUBSTANTIATION: This comment should be accepted as revised in item 4 above, if my comment on 16-223 is accepted. FPL type coaxial cables are not required by the Code to have a substitute.
PANEL ACTION: Reject.

16- 178 - (760-71(b)): Reject
Note: "See Technical Correlating Committee action on Comment 16-98."
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-149
RECOMMENDATION: Delete proposed section 760-71(e) and associated notes.
SUBSTANTIATION: The introduction of a new class of cable ("Limited Combustible Cable") is premature at this time for the following reasons:
A. The note to the definition section 725.71(B), FPN No. 1 references NFPA 90A, Standard for the Installation of Air-Conditioning and Ventilating Systems for the definition of limited combustible. That definition is as follows:
"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141J/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):
a. Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50;
b. Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be combustible."
This definition was established and is applied to <u>building construction materials</u> and not to specific wiring methods or technologies for use in buildings. NFPA 255 and NFPA 259 were never intended for the evaluation of multi-component systems such as electrical and optical cable. More current test methods (other than NFPA 255 and 259), such as NFPA 262, the cone calorimeter, etc. provide reproducible smoke obscuration, flame spread, or heat release (not heat value) information and are more appropriate for measuring the fire hazards of cable. Not all parts of this "Limited Combustible" definition have been applied to the broad scope of cables. Until this definition can be shown as appropriate for cables (attainable and reproducible) it should not be deemed credible and supported by the National Electrical Code

at this time. Referencing this inappropriate definition in the National Electrical Code is misleading and bad code.

B. The note references NFPA 255 as the test standard for smoke developed index. This test is not an appropriate test for cables for the following reasons:

a. NFPA 255 has not been harmonized, as has NFPA 262. NFPA 262 has a proven record, unlike NFPA 255.

b. NFPA 255 is not reproducible, whereas NFPA 262 has been shown to be reproducible. This lack of reproducibility has been demonstrated numerous times in round-robin testing of building materials among multiple labs.

The most recent example of this reproducibility problem has been demonstrated in the Interim Report of the Fire Protection Research Foundation (FPRF) "Limited Combustible Cable" (ex. "Permanent Plenum Cable") project, dated June 2000. This report states "The flame spread and smoke measurements in NFPA 255 show good repeatability but relatively poor reproducibility, i.e., the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error." (Page 9, section 4.1.2). In this case, with only two laboratories participating, errors in reproducibility were in the range of 100 percent. Given that numerous fire-testing tunnels exist, the range of error can be expected to be even larger.

This test is inappropriate for cables as the cables are installed against the top of the tunnel. This orientation is not similar to normal cable installations, and cable placement on top of the wire mesh is random in the tunnel.

C. Cable installed above ceilings does not become involved in the fire until near or at flashover. At that point in the fire development, the ceiling tile is falling to expose the cable. Cables in walls or below floors are generally exposed to the fire conditions even later in the fire development. These cables do not spread flame more than 5 ft when tested in accordance with NFPA 262. The proposed restrictions on cable appear excessive based on the fire record.

D. There is not a need established (fire record or hazard analysis) for a new cable category. There are two research projects that are intended to provide information on the fire hazard of cables. The ASHRAE project has not yet begun. This ASHRAE Project is being conducted by the National Research Council of Canada and is a broad based fire hazard assessment program developed to evaluate the hazard presented by the accumulation of plenum cables. This question has not yet been answered and developing cable categories to address a hazard that has not yet been defined is premature. The project when completed will assist in developing appropriate language for NFPA 90A and/or the National Electrical Code.

The FPRF project has only issued an interim report dated June 2000. This project has only accomplished a cursory review of one cable type in NFPA 255 and NFPA 259 and has just begun the experimental work on broader aspects of the "limited combustible" definition.

The proposals for the National Electrical Code that have been accepted by Code Making Panel 16 for the removal of all abandoned cable broadly addresses this problem now. The adoption of these proposals for removing all abandoned cable will significantly reduce the fuel load created by excessive cable accumulation.

E. The International Mechanical Code (IMC), the Uniform Mechanical Code (UMC), and the NFPA 90A (the membership and the NFPA Standards Council) have each recently rejected similar provisions to the ones being proposed for the National Electrical Code. These proposals for "limited combustible cables" have been rejected for several reasons including:

a. They will present confusion in the field;

b. They are not good code based on sound engineering principles;

c. They are not based on good fire hazard assessment information; and

d. Questions regarding the appropriateness and accuracy of the test protocols NFPA 255 and NFPA 259.

(Log #1067)

16- 183 - (760-71(e)): Reject
SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.
COMMENT ON PROPOSAL NO: 16-151
RECOMMENDATION: This proposal should be rejected, the new section 760-71(e) should not be created and the FPLP-50 classification should not be created.
SUBSTANTIATION: The FPLP-50 classification is an unnecessary classification because it is not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}
* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}

* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}

* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.

* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."

* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $-C\,H_2- + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2\,H_3\,Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2\,H_3\,Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\,H_2O + 0.5\,N_2 + 1.25\,O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a\,H_b\,O_c\,F_e + (a+b/4-c/2-e/4)\,O_2 + (n+1/2)*e*(1-x) - b/2)\,H_2O = (a-ex/4)\,CO_2 + ex/4\,CF_4 + e(1-x)\,(HF) + e(1-x)\,n\,H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz,

stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

Note: "See Technical Correlating Committee action on Comment 16-98."

SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.

COMMENT ON PROPOSAL NO: 16-149

RECOMMENDATION: This proposal should be rejected, the new section 760-71(e) should not be created and the FPLP-50 classification should not be created.

SUBSTANTIATION: The FPLP-50 classification is unnecessary classification because it is not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}
* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces

involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}

* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}

* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}

* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.

* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."

* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $- C H_2 - + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2 H_3 Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2 H_3 Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference

between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\ H_2O + 0.5\ N_2 + 1.25\ O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a H_b O_c F_e + (a+b/4-c/2-e/4)\ O_2 + (n+1/2)*e*(1-x) -b/2)\ H_2O = (a-ex/4)\ CO_2 + + ex/4\ CF_4 + e(1-x)\ (HF) + e(1-x)\ n\ H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

16- 186 - (Table 760-71(i)): Reject

Note: "See Technical Correlating Committee action on Comment 16-98."

SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.

COMMENT ON PROPOSAL NO: 16-152

RECOMMENDATION: This proposal should be rejected, the references to FPLP-50 should be deleted from the Table 760-7(i) and the FPLP-50 classification should not be created.

SUBSTANTIATION: The FPLP-50 classification is an unnecessary classification because it is not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of

plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}
* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}

* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.
* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."
* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building

construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $- C\,H_2 - + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2\,H_3\,Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2\,H_3\,Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\,H_2O + 0.5\,N_2 + 1.25\,O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a\,H_b\,O_c\,F_e + (a+b/4-c/2-e/4)\,O_2 + (n+1/2)*e*(1-x) - b/2)\,H_2O = (a-ex/4)\,CO_2 + ex/4\,CF_4 + e(1-x)\,(HF) + e(1-x)\,n\,H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

ARTICLE 770 — OPTICAL FIBER CABLES AND RACEWAYS

(Log #300)

16- 188 - (770-2 Abandoned Cable (New)): Accept in Principle
SUBMITTER: Gerald Lee Dorna, Belden Wire & Cable Co.
COMMENT ON PROPOSAL NO: 16-154
RECOMMENDATION: The definition of "Abandoned Cable" should be the same here as what we accepted in Proposal 16-273. It should be:
"Cable that is neither terminated at ~~both ends, at a connector or other~~ equipment, not identified for future use with a tag."
This is the same wording we accepted for Proposal 16-273.
SUBSTANTIATION: The reason we took out the reference to connectors in Proposal 16-273 is because CATV cable usually has connectors attached. It was our concern that CATV cables would have connectors attached and then would not fall under the definition the panel had accepted in principal. If we make the definition the same as I have suggested above then it will make it irrelevant on whether the cable has connectors or not. I can foresee someone using the fact that the cable has a connector on it, therefore it does not fall under "abandoned cable" and does not need to be removed.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-190.

(Log #458)

16- 189 - (770-2, Abandoned Cable): Accept in Principle in Part
SUBMITTER: Technical Correlating Committee on Signaling Systems for the Protection of Life and Property
COMMENT ON PROPOSAL NO: 16-154
RECOMMENDATION: Revise the proposed definition of abandoned cable to read as follows:
"Cable that is neither terminated at equipment, nor identified for future use with a dated tag."
SUBSTANTIATION: The definition proposed for 820-2 by the Panel Action of Proposal 16-273 is clear and concise and should be used consistently in all Articles. This proposed definition has been modified in the above recommendation to add the word "dated" before the word "tag." The tag should be dated so the authority having jurisdiction can determine the date on which the cable was designated for future use. This will establish a means to allow the decision of abandonment to be re-evaluated periodically if the authority having jurisdiction so desires.
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-190. Panel statement on Comment 16-246 includes the explanation for the rejected part.

16- 190 - (770-2): Accept in Principle
SUBMITTER: Robert W. Jensen, dbi-Telecommunications Infrastructure Design
COMMENT ON PROPOSAL NO: 16-154
RECOMMENDATION: New wording:
Abandoned Cable. Installed cable that is neither terminated at both ends at a connector or other equipment, nor identified for future use with a tag.
SUBSTANTIATION: BICSI added the word installed to show that the cable needs to be installed and not in the installers truck. We retained "terminated at both ends" because optical fiber cable is typically terminated at both ends when it is in use (i.e., when not abandoned).
PANEL ACTION: Accept in Principle.
Revise the recommendation to read as follows:
"Abandoned Optical Fiber Cable. Installed optical fiber cable that is not terminated at equipment other than a connector and not identified for future use with a tag."
PANEL STATEMENT: The revised text clearly expresses the intended definition, correlates with similar definitions in other articles and complies with the Manual of Style.

16- 192 - (770-2-Abandoned Cable): Accept in Principle
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-154
RECOMMENDATION: Revise text to read as follows:
Abandoned Cable: Cable that is <u>not</u> ~~neither~~ terminated at both ends, ~~at a connector or other~~ <u>not connected to</u> equipment, <u>or not</u> ~~nor~~ identified for future use with a tag.
SUBSTANTIATION: The term "terminated at a connector" may result in cables being left in place as many cables come with connectors or the installer could add crimp connectors and leave the cables in place. The present language can be easily misunderstood: does the cable have to be terminated and tagged, or is it a choice?
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-190.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:

(Log #305)

16- 195 - (770-3(a)): Accept in Principle
SUBMITTER: Stanley Kaufman, Lucent Technologies
COMMENT ON PROPOSAL NO: 16-176
RECOMMENDATION: Revise 770-3 to read:
770-3. Locations and Other Articles. Circuits and equipment shall comply with (a) and (b). Only those sections of Article 300 referenced in this article shall apply to optical fiber cables and raceways.
(a) Spread of Fire or Products of Combustion. ~~See~~ The requirements of Section 300-21 for electrical installations shall also apply to installations of optical fiber cables and raceways. Abandoned cables shall not be permitted to remain.
(b) Ducts, Plenums, and Other Air-Handling Spaces. The requirements of Section 300-22 for electric wiring, shall also apply to installations of optical fiber cables and raceways where they are installed in ducts or plenums or other space used for environmental air.
Exception to (b): As permitted in Section 770-53(a).
SUBSTANTIATION: Sections 300-21 and 300-22 apply to electrical installations. The revised wording clarifies that the same principles should apply to optical fiber cable and raceways. Also, it is redundant to state "Abandoned cables not intended for future use...", since abandoned cables are defined as not being intended for future use.
PANEL ACTION: Accept in Principle.
In the submitter's recommendation change the second sentence of 770-3(a) to read:
"The accessible portion of abandoned optical fiber cables shall not be permitted to remain."
The balance of the recommendation remains unchanged.
PANEL STATEMENT: The text was revised to correlate with similar requirements in other sections (e.g. see Comment 16-83).

(Log #1581)

16- 196 - (770-3(a)): Accept in Principle in Part
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-176
RECOMMENDATION: Revise text to read as follows:
Spread of Fire or Products of Combustion. Installations in hollow spaces, vertical shafts, and ventilation or air-handling ducts shall be made so that the possible spread of fire or products of combustion will not be substantially increased. Openings around penetrations through fire resistance-rated walls, partitions, floors, or ceilings shall be firestopped using approved methods to maintain the fire resistance rating.
Abandoned cables not intended for future use shall not be permitted to remain.
FPN: Directories of electrical construction materials published by qualified testing laboratories contain many listing installation restrictions necessary to maintain the fire-resistive rating of assemblies where penetrations or openings are made.
SUBSTANTIATION: This definition under the section entitled "Spread of Fire or Products of Combustion" is not consistent throughout the Code. This comment uses language from ROP 16-250 [850-52(B)] to provide a consistent requirement throughout the code.
The same comment is being made for the following sections:
640-3A (ROP 16-1a)
645-5D6 (ROP 12-106)
725-3B (ROP 16-80)
760-3A (ROP 16-144)
820-3A (ROP 16-313)
820-52B (ROP 16-311)
830-3A (ROP 16-364)
830-58B (ROP 16-368)
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: The panel accepts in principle the statement regarding abandoned cables. Refer to panel action on Comment 16-195. This satisfies the submitter's concerns.
The current reference to 300-21 satisfies the balance of the comment, which is rejected. That portion of the comment repeats the text of 300-21.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:
AFFIRMATIVE: 21

(Log #1417)

16- 197 - (770-3(b)): Reject
SUBMITTER: Kari Barrett, American Chemistry Council
COMMENT ON PROPOSAL NO: 16-176
RECOMMENDATION: Delete the following text:
~~Abandoned cables not intended for future use shall not be permitted to remain.~~
SUBSTANTIATION: Removal of abandoned cables in these areas is a "housekeeping" issue. Whether or not to remove them should be the owner's decision and not be mandated by the NEC.
PANEL ACTION: Reject.
PANEL STATEMENT: The panel reaffirms that removal of abandoned cables addresses a significant fire safety issue. The term "housekeeping" is not applicable to abandoned cables. Fire safety and cable installation are within the scope of the NEC.

16- 198 - (770-5(b)(2) (New)): Accept in Principle in Part
SUBMITTER: Marcelo M. Hirschler, GBH International
COMMENT ON PROPOSAL NO: 16-159
RECOMMENDATION: Revise text as follows:
770-5. Access to Electrical Equipment Behind Panels Designed to Allow Access
Access to equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).
a. New building construction (e.g. renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.
b. Buildings with existing cable systems. Where practicable, installation of cables shall comply with Section 300.11. Where impracticable to comply with Section 300.11, in those areas having

ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables less than 13 mm (0.5 in) in diameter, between access points in the ceiling. ~~cables less than 13 mm (0.5 in) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.~~

~~1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.~~

~~2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.~~

SUBSTANTIATION: The permission granted by the panel to install cables on suspended ceiling tiles should be rescinded. Neither cables nor any other item should be installed on top of a suspended ceiling tile. The support systems of suspended ceilings are not designed to resist any significant amount of weight without being deflected or broken.

This issue has been raised on Proposal 16-192 (log 1665) in negative comments by two panel members, Mr Egesdal and Mr Speer, who both correctly point out that suspended ceiling tiles are not intended to support the weight of electrical cables. Mr. Sandy Egesdal repeats his negative comment on this proposal.

The point made by the Technical Correlating Committee on proposal 16-38 that such use would constitute an exposed use of cables is an additional consideration to rejecting this part of the proposal.

PANEL ACTION: Accept in Principle in Part.

The panel accepts the principle of permitting a limited number of cables to be installed in a fixed or hard ceiling. The panel rejects the balance of the submitter's recommendation including the limiting of the installation of cables in a suspended lay-in ceiling.

PANEL STATEMENT: The recommendation of Comment 16-199a provides a reasonable, safe, and practical solution to placing a limited number of unsupported optical fiber cables in existing construction.

EXPLANATION OF NEGATIVE:

SPEER: See my explanation of negative vote on Comment 16-27a.

(Log #1638)

16- 199 - (770-6): Reject

SUBMITTER: Andy Scott, National Cable Television Association

COMMENT ON PROPOSAL NO: 16-159a

RECOMMENDATION: Reject Proposal 16-159a.

SUBSTANTIATION: NCTA, on behalf of the cable television industry, strongly urges Panel 16 to reject these proposals. While attachment every 5 ft may be a practice in many cases, it also may be overly restrictive and unnecessary in others. The requirement to support cables every 5 ft is outside the scope of the code. The NCTA urges Panel 16 not to allow the NEC to serve as an Installation Manual.

PANEL ACTION: Reject.

PANEL STATEMENT: The panel action on Comment 16-212 addresses the concerns in the submitter's substantiation.

NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21

VOTE ON PANEL ACTION:

AFFIRMATIVE: 21

(Log #CC1604)

16- 199a - (770-7): Accept

Note: The Technical Correlating Committee directs that the references to Articles 640 and 650 be deleted because the panel did not accept similar requirements in those articles. The Technical Correlating Committee also directs that the FPN which contains a mandatory requirement be deleted to comply with the NEC Style Manual.

SUBMITTER: CMP 16

COMMENT ON PROPOSAL NO: 16-159

RECOMMENDATION: Retain the existing 1999 code text for Section 770-7 (unmodified).

Add new Section 770.9 to read as follows:

770.9 Installation of Cables.

Optical fiber cables shall be installed in compliance with A or B.

A. New Ceiling Construction. The installation of cables in new ceiling construction shall comply with Section 300-11.

B. Existing Ceilings.

1. Fire-Rated Ceilings. The installation of cables in the cavity of an existing fire-rated ceiling assembly shall comply with Section 300-11.

2. Non-Fire-Rated Ceilings. For installations in the cavity of an existing non-fire-rated ceiling assembly, cables less than 6 mm (0.25 in) in diameter shall be permitted to be installed unsupported from the building structure in accordance with the following:

a. Fixed or Hard Ceilings. In areas having fixed or hard ceilings with access points or access panels, a combined total of three cables from Articles 640, 650, 725, 760, 770, 800, 820 and 830, shall be permitted to be placed between access points or access panels in the ceiling. Additional cables shall be installed in accordance with 300.11.

b. Suspended Lay-In Ceilings. In areas having suspended lay-in ceilings, in any 3 m by 3m (10 ft. x 10 ft) ceiling area, a combined total of three cables from Articles 640, 650, 725, 760, 770, 800, 820 and 830, shall be permitted to be installed directly on the ceiling grid. Additional cables shall be installed in accordance with 300.11.

FPN. Cables of all types are included in the total limit of three cables, not three cables from each article.

SUBSTANTIATION: Proposal 16-159 was accepted in principle to permit the installation of unsupported cables under limited conditions. Proposal 16-159 text, however, was too broad and unclear. The text of this comment clarifies the original intent. The new text includes requirements to comply with Section 300.11. Permitted installation conditions will not compromise the integrity of fire-rated ceilings. For non-fire-rated ceilings, the permitted relief from Section 300.11 is limited to very specific conditions. Section 770-7 is not being modified because the accessibility requirements should remain.

PANEL ACTION: Accept.

16- 201 - (770-7): Reject

SUBMITTER: Glenn W. Zieseniss, Crown Point, IN

COMMENT ON PROPOSAL NO: 16-159

RECOMMENDATION: Change the "Accept in Principle" to "Reject".

SUBSTANTIATION: I agree with Mr. Egesdal's and Mr. Speer's negative vote and comment on Proposal 16-192. This proposal is giving a "blanket okay for any type of ceiling tile to support the possible added weight of 3 cables of less than 1/2 in. in diameter on each ceiling tile. The proposal does not affirm that the ceiling

tile industry was contacted of adding weight to lay on their product. This product is not part of the building structure, and is not designed to be suitable for supporting cables. I have seen ceiling tiles which look as if made of fiber glass insulation which has a finished surface on the exposed side of the ceiling. It is my belief that this ceiling tile would not accept additional weight upon it. I have contacted three ceiling tile companies or organizations on this proposal. They all suggested that their ceiling tiles are not to support additional weight. I have provided copies of my e-mail contacts.

NOTE: Supporting Material is available at NFPA Headquarters.

PANEL ACTION: Reject.

PANEL STATEMENT: The recommendation of Comment 16-199a provides a reasonable, safe, and practical solution to placing a limited number of unsupported optical fiber cables in existing construction. The restrictions contained in Comment 16-199a limit both the number and size of wires and cables permitted on each ceiling panel, thereby controlling weight and accumulation so that cables can be easily moved aside to permit access. The submitter's concern about weight is addressed by decreasing the size of the cable to 1/4 inch and limiting the number of cables to three per each 10 ft x 10 ft area.

(Log #860)

16- 202 - (770-7): Accept in Principle in Part

SUBMITTER: Larry F. Miller, National Electrical Manufacturers Association (NEMA)

COMMENT ON PROPOSAL NO: 16-159

RECOMMENDATION: The panel should continue to Accept the proposal in Principle but revise the Panel Action text to read as follows:

770-7. Access to Electrical Equipment Behind Panels Designed to Allow Access.

Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use or maintenance. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.

b1. Installation of cables in suspended lay-in type ceiling spaces shall comply with 300.11..

2. Installation of cables in other than suspended lay-in type ceiling spaces shall comply with 300.11 where the space is accessible.

3. Where the ceiling is not the lay-in type, and the space is not accessible, three cables less than 13 mm (0.5 in.) shall be permitted to be installed unsupported by the building structure between access points or access panels.

~~Buildings with existing cabling systems.~~

~~Where practicable, installation of cables shall comply with Section 300.11. Where impracticable to comply with Section 300.11, cables less than 13 mm (0.5 in) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.~~

~~1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.~~

~~2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum three supported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid."~~

SUBSTANTIATION: We agree with Mr. Egedsal's and Mr. Speer's negative comments that suspended ceilings are not intended to support electrical wires or cables.

Section 300-11(a)(1) (wiring located within the cavity of a fire-rated floor-ceiling or roof-ceiling) allows an exception for wiring that has been tested as part of the fire-rated assembly. This proposal could compromise the fire-rating of the ceiling by overriding that requirement. The words "or maintenance" have been added because so much of the damage occurs in ceiling spaces as various trades perform maintenance.

The submitter states that he has submitted companion proposals for Articles 725 760, 770, 820 and 830. If each of these articles will allow three cables per ceiling tile, this could result in a total of 18 cables per ceiling tile, which appears to be approaching the "excessive accumulation" the submitter agrees could be a hazard. Limiting the size and quantity of cable permitted to be fished in non-lay-in ceiling spaces will help control the weight of cable (combined with that permitted in the other articles referenced above) on these ceilings.

PANEL ACTION: Accept in Principle in Part.

The panel rejects the recommended addition of the word "maintenance." The balance of the recommendation is accepted in principle.

PANEL STATEMENT: The term "normal building use" includes "maintenance." Refer to the recommendation and substantiation on Comment 16-199a.

(Log #967)

16- 203 - (770-7): Accept in Part

SUBMITTER: Palmer Hickman, Royersford, PA

COMMENT ON PROPOSAL NO: 16-159

RECOMMENDATION: Reject Proposal 16-159 and retain present 770-7 as it appears in the 1999 NEC.

SUBSTANTIATION: I would strongly urge Code-Making Panel 16 to reconsider their action on this proposal. The proposed 770.7(B)(2) would now permit three cables to be installed on the tiles of a suspended ceiling, without providing any technical substantiation for this allowance.

I offer the following reasons against accepting this proposal:

1) Chapters 1-4 apply except as amended by Chapters 5, 6 and 7. Sections 300-11(a)(1) and (2) state wiring shall not be supported by the ceiling assembly.

2) Section 770-7 deals with access to electrical equipment, not support of wiring.

3) Code-Making Panel 3 reaffirmed their prohibition of ceiling assemblies being used beyond the manufacturers design parameters in the Panel Statement to Comments 3-53 and 3-57 of the 1998 ROC, and Proposal 3-68 of the 2001 ROP. In the latter reference, Code-Making Panel 3 states: "The panel re-affirms its position that an independent means of support shall be provided for all wiring, not just branch circuit wiring...".

I understand that his proposed allowance of ceiling support only applies to buildings with existing cabling systems where it is "impracticable" to comply with 300-11. Impracticability does not provide technical substantiation to allow a ceiling assembly that has not been evaluated to support the potential additional load of three cables on each and every ceiling tile. Essentially, the ceiling assembly is expected to carry the additional load of potentially hundreds of cables installed directly on it. As an example, a 100'x100' room with a suspended ceiling using 2'x2' tiles, would be expected to carry the full weight of 150 cables.

The substantiation provided by Mr. Brunssen for his proposal does not support the proposed change as amended by Code-Making Panel 16. He claims that "a limited amount of cabling laid directly on a suspended ceiling is permitted..." without stating where this permission is given, and by whom. The entire substantiation of the submitter seems contrary to the action of the panel. I am not sure he would recognize the end result as the proposal he made. Mr. Brunssen begins his substantiation by stating "Section 770-7 may be misinterpreted to mean that cables may not be placed directly on suspended ceilings." He notes that the 1999 NEC Handbook "Figures 725-2 and 725-3 lead the reader to conclude that cables are permitted to rest directly on the suspended ceiling." The submitter also stated Code-Making Panel 16 responded to a proposal to Article 725 (1992 TCD Comment 16-18) that the proposed requirement "...would still allow some cabling of a limited quantity above the ceiling tile, but not to an excessive amount." Note the words "above the ceiling tile", not on the ceiling tile. I feel these examples are not misinterpretations, but rather correct interpretations, and substantiation to reject his proposal.

In conclusion, I respectfully disagree with the Panel Action on this Proposal. I find no technical substantiation to warrant such a dramatic change. Mr. Brunssen presented a well-researched proposal addressing access, not support. The substantiation of the

submitter does not support his change, nor does the Panel Statement.
PANEL ACTION: Accept in Part.
The panel accepts the portion of the comment to retain Section 770.7, and rejects the portion of the comment to reject Proposal 16-159.
PANEL STATEMENT: Refer to the recommendation and substantiation on Comment 16-199a. Also refer to the panel action and statement on Comment 16-201.

16- 204 - (770-7): Accept in Principle
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-159
RECOMMENDATION: Revise as follows:
770-7. Access to Electrical Equipment Behind Panels Designed to Allow Access. Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).
a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.
b. Buildings with existing cabling systems. Where practicable, installation of cables shall comply with Section 300-11. Where impracticable to comply with Section 300-11, cables less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.
1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.
2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of ~~any one~~ each ceiling tile, i.e., up to three wires and cables are permitted to lay on a ceiling tile. The cables shall be run parallel to the ceiling grid.
SUBSTANTIATION: Proposed Section 770-7(b)(2), as presently written in Proposal 16-159, panel action, is confusing and could be interpreted as permitting a total of only three unsupported wires and cables above a suspended ceiling. The intent of the panel was that up to a maximum of three unsupported wires and cables may be routed across each and every ceiling tile. The revision proposed in this comment clarifies and accomplishes the intent of the panel. This is a companion comment and is intended to correlate with comments on Proposals 16-38, 16-112, 16-192, 16-276, and 16-332.

16- 205 - (770-7): Accept in Principle
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-159
RECOMMENDATION: Continue to accept in principle.
SUBSTANTIATION: Panel 16 should continue to accept in principle as it provides a reasonable and safe solution to placing a limited number of signaling and communications wires and cables in existing construction. The restrictions contained in the proposed change limit both the number and size of wires and cables permitted on each suspended ceiling panel. In this manner additional weight, as well as an accumulation of wires and cables that would otherwise restrict access above suspended ceiling panels, is controlled and limited. The limited number of cables permitted can easily be moved aside to permit access. Some concern has also been expressed that cables placed directly on the ceiling panels would degrade the fire rating of the ceiling. The suspended ceiling, part of a membrane that is intended to retard fire from spreading into the ceiling cavity, would be unaffected in its ability to retard the spread of fire by a limited number of wires and cables resting on top of the panels. This is a companion comment and is intended to correlate with comments on Proposals 16-38, 16-112, 16-192, 16-276, and 16-332.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to the substantiation on Comment 16-199a. This action meets the intent of the submitter.

(Log #742)

16- 209 - (770-7(b)): Accept in Principle in Part
SUBMITTER: Richard P. Owen, City of St. Paul, Electrical Inspection
COMMENT ON PROPOSAL NO: 16-159
RECOMMENDATION: Replace (b) of the proposal with the following text:

(b) Buildings not Covered Under (a) Above. In areas having ceilings with access points or panels and having 900 mm (3 ft) or less vertical clearance above the ceiling, it shall be permissible to fish a maximum of 3 cables, each less than 13 mm (0.5 in.) in diameter, between access points in the ceiling.

SUBSTANTIATION: The Technical Correlating Committee directed Panel 3 Chair Raymond Weber to form a Task Group to review these proposals and to submit the results as comments to Panel 16. Task Group 3-16, consisting of Chair Weber, members Steven Speer; Lee Hewitt; Richard Owen and Ron Maassen held a conference call on October 3, 2000 and developed the above language as a comment. The Task Group was concerned with allowing unsupported cabling above suspended ceilings, since companion proposals for Articles 725, 760, 770, 800, 820 and 830 would also allow this limited cabling without support. The possible accumulation of cable allowed by all these articles would be excessive and would both limit access to a ceiling and conflict with Section 300.11. Rewording of (b) also eliminated the unenforceable terms "practicable" and "impracticable" as directed by the Technical Correlating Committee.
PANEL ACTION: Accept in Principle in Part.
The panel rejects the specific limitations in the comment but accepts the principle of permitting a limited number of cables.
PANEL STATEMENT: The recommendation of Comment 16-199a provides a reasonable, safe, and practical solution to placing a limited number of unsupported optical fiber cables in existing construction.

(Log #1256)

16- 210 - (770-7(b)(2)): Reject
SUBMITTER: J. Paul Spinn, USG Research & Technology Center
COMMENT ON PROPOSAL NO: 16-159
RECOMMENDATION: Delete the following text:

In areas having suspended lay in ceiling, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.

SUBSTANTIATION: By allowing a maximum of three unsupported cables on top of any one (or more) ceiling tiles, the fire-rating of the assembly and the Class A surface burning characteristic requirement, which includes flame spread and smoke development, could be jeopardized. By decreasing the fire-rating of the plenum assembly and the surface burning characteristic of the ceiling tile, the life safety of the occupants can be negatively affected. By rejecting this proposal, these problems can be eliminated.

To substantiate the comment made for the proposal, four key points are provided:

[1] For a fire rated floor/ceiling or roof/ceiling assembly, placement of unsupported cables on top of any one ceiling tile or a row of ceiling tiles could invalidate the fire-rating for a particular assembly. The rationale for this argument are:
(a) The weight of the cables could cause premature tile fallout leading to an early failure of the assembly, which is tested in accordance with NFPA 251 or ASTM E 119.
(b) The increased heat of combustion associated with the cable jackets, which commonly use plastics, will add to the total fire load of an assembly. As the total fire load increases for an assembly, the fire endurance of the assembly will decrease, which could jeopardize an assembly's fire-rating.

[2] For a Class A ceiling, placement of unsupported cables on the ceiling can effect flame spread and smoke development performance and jeopardize the required Class A rating for the ceiling tiles. The rationale for this argument are:
(a) The flame spread will increase due to the increased total heat load, which is caused by the plastic on the cable jacket.
(b) The smoke development will increase due to the cable jackets, which are usually plastic such as PVC or CPVC.

[3] The placement of unsupported cables on top of any one or more ceiling tiles presents potential life safety issues for occupants due to the decreased fire-rating of the floor/ceiling or roof/ceiling or an increase in the ceiling surface burning characteristics.

[4] Placement of unsupported cables on top of any one ceiling tile or a row of ceiling tiles would increase ceiling tile sag due to increased weight of the cables on the ceiling tiles, and would impair the accessibility of the ceiling plenum.

PANEL ACTION: Reject.
PANEL STATEMENT: The recommendation of Comment 16-199a provides a reasonable, safe, and practical solution to placing a limited number of unsupported optical fiber cables in existing construction. The restrictions contained in Comment 16-199a limit both the number and size of cables permitted on each ceiling panel, thereby controlling weight and accumulation so that cables can be easily moved aside to permit access. The submitter's concern about weight is addressed by decreasing the size of the cable to 1/4 inch and limiting the number of cables to three per each 10 ft x 10 ft area. The revised text precludes the installation of cables in all fire-rated ceiling assemblies.

16- 211 - (770-8): Reject
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-159a
RECOMMENDATION: Delete 770-8 and incorporate the information in 770-7 as follows:

770-7. ~~Access to Electrical Equipment Behind Panels Designed to Allow Access.~~ Mechanical Execution of Work. Optical fiber cables shall be installed in a neat and workmanlike manner. Access to electrical equipment shall not be denied by an accumulation of ~~wires and~~ cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. ~~Access to electrical equipment behind ceilings designed to allow access~~Cables installed exposed shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11. Cables shall be supported by structural components of the building. Such cables shall be attached to structural components at intervals not exceeding 1.52 m (5 ft) and within 305 mm (12 in.) from every cabinet, box or fitting by straps, staples, hangers or similar fittings designed and installed so as not to damage the cable. The installation shall also conform with Section 300-4(d).

b. Buildings with existing cabling systems. Where practicable, installation of cables shall comply with ~~Section 300-11~~ 760-5(a). Where impracticable to comply with ~~Section 300-11~~ 770-7(a)., cables less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.

1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.

2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.

Continue to delete the fine print note as proposed in Proposal 16-159a.

SUBSTANTIATION: This is a companion comment and is intended to correlate with similar comments on Proposals 16-39, 16-115, 16-192a, 16-276a, and 16-333a. Sections 770-7 and 770-8 actually address the same issue, the mechanical execution of work. Accessibility behind panels designed to allow access is really an "execution of work" issue. Additionally, the Technical Correlating Committee has identified a potential conflict between the panel action on Proposals 16-38 and 16-39, that would also result here in 770. This comment editorially combines 770-7 and 770-8 into a single Section 770-5 requiring attachment to the building structure of exposed cables and conductors and, where impracticable to do so, permits a limited number of cables of specified maximum size to be placed on suspended ceiling tiles. It accommodates the intent of both proposals that cables should be supported by the building structure, but in extenuating circumstances in existing construction, a limited number and weight of cables may be placed on a suspended ceiling. Further, in the first paragraph of 770-7, the phrase "wires and" is deleted as there are no optical fiber "wires".

PANEL ACTION: Reject.

PANEL STATEMENT: The sections should not be combined. Refer to the recommendation and substantiation for Comment 16-199a where these recommendations are addressed.

COMMENT ON PROPOSAL NO: 16-159a

RECOMMENDATION: Delete the following text:

~~Such cables shall be attached to structural components at intervals not exceeding 1.52 m (5 ft) and within 305 mm (12 In.) from every cabinet, box or fitting by straps, staples, hangers or similar fittings designed and installed so as not to damage the cable. The installation shall also conform with Section 300-4(d).~~

SUBSTANTIATION: The addition of this text would make the mandatory requirements of this section overly specific. The present wording is sufficient guidance to both the installer and the authority having jurisdiction.

PANEL ACTION: Accept in Part.

Revise the third sentence of the panel action text of Proposal 16-159a to read as follows:

"Such cables shall be attached to structural components by straps, staples, hangers or similar fittings designed and installed so as not to damage the cable."

PANEL STATEMENT: The panel accepts the removal of specific distances for the attachment of the cable. The panel does not agree that the existing code wording is sufficient guidance to both the installer and the authority having jurisdiction.

SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.

COMMENT ON PROPOSAL NO: 16-162

RECOMMENDATION: This proposal should be rejected, the references to OFNP-50 and OFCP-50 should be deleted from the Table 770-50 and the OFNP-50 and OFCP-50 classifications should not be created.

SUBSTANTIATION: The OFNP-50 and OFCP-50 classifications are unnecessary classification because they are not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}
* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are

the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}

* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}

* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}

* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.

* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."

* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $- C\,H_2 - + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2\,H_3\,Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2\,H_3\,Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while

furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\ H_2O + 0.5\ N_2 + 1.25\ O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a H_b O_c F_e + (a+b/4-c/2-e/4)\ O_2 + (n+1/2)*e*(1-x) - b/2)\ H_2O = (a-ex/4)\ CO_2 + ex/4\ CF_4 + e(1-x)\ (HF) + e(1-x)\ n\ H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

Note: "See Technical Correlating Committee action on Comment 16-98."

SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.

COMMENT ON PROPOSAL NO: 16-169

RECOMMENDATION: This proposal should be rejected, the new section 770-51(b) should not be created and the OFNP-50 and OFCP-50 classifications should not be created.

SUBSTANTIATION: The OFNP-50 and OFCP-50 classifications are unnecessary classifications because they are not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}
* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}

* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.

* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."

* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $- C\,H_2 - + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2\,H_3\,Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2\,H_3\,Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\,H_2O + 0.5\,N_2 + 1.25\,O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a\,H_b\,O_c\,F_e + (a+b/4-c/2-e/4)\,O_2 + (n+1/2)*e*(1-x) - b/2)\,H_2O = (a-ex/4)\,CO_2 + ex/4\,CF_4 + e(1-x)\,(HF) + e(1-x)\,n\,H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid

formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

(Log #1588)

16- 224 - (770-51(b)): Reject
Note: "See Technical Correlating Committee action on Comment 16-98."
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-169
RECOMMENDATION: Delete proposed section 770-51(b) and associated notes.
SUBSTANTIATION: The introduction of a new class of cable ("Limited Combustible Cable") is premature at this time for the following reasons:

A. The note to the definition section 725.71(B), FPN No. 1 references NFPA 90A, Standard for the Installation of Air-Conditioning and Ventilating Systems for the definition of limited combustible. That definition is as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141J/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

a. Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50;

b. Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be combustible."

This definition was established and is applied to <u>building construction materials</u> and not to specific wiring methods or technologies for use in buildings. NFPA 255 and NFPA 259 were never intended for the evaluation of multi-component systems such as electrical and optical cable. More current test methods (other than NFPA 255 and 259), such as NFPA 262, the cone calorimeter, etc. provide reproducible smoke obscuration, flame spread, or heat release (not heat value) information and are more appropriate for measuring the fire hazards of cable. Not all parts of this "Limited Combustible" definition have been applied to the broad scope of cables. Until this definition can be shown as appropriate for cables (attainable and reproducible) it should not be deemed credible and supported by the National Electrical Code at this time. Referencing this inappropriate definition in the National Electrical Code is misleading and bad code.

B. The note references NFPA 255 as the test standard for smoke developed index. This test is not an appropriate test for cables for the following reasons:

a. NFPA 255 has not been harmonized, as has NFPA 262. NFPA 262 has a proven record, unlike NFPA 255.

b. NFPA 255 is not reproducible, whereas NFPA 262 has been shown to be reproducible. This lack of reproducibility has been demonstrated numerous times in round-robin testing of building materials among multiple labs.

The most recent example of this reproducibility problem has been demonstrated in the Interim Report of the Fire Protection Research Foundation (FPRF) "Limited Combustible Cable" (ex. "Permanent Plenum Cable") project, dated June 2000. This report states "The flame spread and smoke measurements in NFPA 255 show good repeatability but relatively poor reproducibility, i.e., the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error." (Page 9, section 4.1.2). In this case, with only two laboratories participating, errors in reproducibility were in the range of 100 percent. Given that numerous fire-testing tunnels exist, the range of error can be expected to be even larger.

This test is inappropriate for cables as the cables are installed against the top of the tunnel. This orientation is not similar to normal cable installations, and cable placement on top of the wire mesh is random in the tunnel.

C. Cable installed above ceilings does not become involved in the fire until near or at flashover. At that point in the fire development, the ceiling tile is falling to expose the cable. Cables in walls or below floors are generally exposed to the fire conditions even later in the fire development. These cables do not spread flame more than 5 ft when tested in accordance with NFPA 262. The proposed restrictions on cable appear excessive based on the fire record.

D. There is not a need established (fire record or hazard analysis) for a new cable category. There are two research projects that are intended to provide information on the fire hazard of cables. The ASHRAE project has not yet begun. This ASHRAE Project is being conducted by the National Research Council of Canada and is a broad based fire hazard assessment program developed to evaluate the hazard presented by the accumulation of plenum cables. This question has not yet been answered and developing cable categories to address a hazard that has not yet been defined is premature. The project when completed will assist in developing appropriate language for NFPA 90A and/or the National Electrical Code.

The FPRF project has only issued an interim report dated June 2000. This project has only accomplished a cursory review of one cable type in NFPA 255 and NFPA 259 and has just begun the experimental work on broader aspects of the "limited combustible" definition.

The proposals for the National Electrical Code that have been accepted by Code Making Panel 16 for the removal of all abandoned cable broadly addresses this problem now. The adoption of these proposals for removing all abandoned cable will significantly reduce the fuel load created by excessive cable accumulation.

E. The International Mechanical Code (IMC), the Uniform Mechanical Code (UMC), and the NFPA 90A (the membership and the NFPA Standards Council) have each recently rejected

similar provisions to the ones being proposed for the National Electrical Code. These proposals for "limited combustible cables" have been rejected for several reasons including:
a. They will present confusion in the field;
b. They are not good code based on sound engineering principles;
c. They are not based on good fire hazard assessment information; and
d. Questions regarding the appropriateness and accuracy of the test protocols NFPA 255 and NFPA 259.

16- 229 - (770-52(d) (New)): Accept
SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.
COMMENT ON PROPOSAL NO: 16-73
RECOMMENDATION: Continue rejecting the exception for permitting cable to be listed as limited combustible to remain in plenums, in particular OFNP-50 and OFCP-50.
SUBSTANTIATION: Materials that are limited combustible can burn (i.e. they are not noncombustible) and increase the fire load. Therefore, there is a potential for increased fire hazard or fire risk when any cable, irrespective of whether it is or is not limited combustible, remains as fuel load unnecessarily once it has been taken out of use. Furthermore, all abandoned cables can also affect the safety of plenums because of their weight. There is, thus, no justification for permitting a "limited combustible" cable to remain in a plenum once it is abandoned and not intended for future use.
PANEL ACTION: Accept.

16- 236 - (770-53): Reject
Note: "See Technical Correlating Committee action on Comment 16-98."
SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.
COMMENT ON PROPOSAL NO: 16-177
RECOMMENDATION: This proposal should be rejected, the references to OFNP-50 and OFCP-50 should be deleted from the Table 770-53 and not incorporated into Figure 770-53 and the OFNP-50 and OFCP-50 classifications should not be created.
SUBSTANTIATION: The OFNP-50 and OFCP-50 classifications are unnecessary classification because they are not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire

performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}
* "Non residentia1 concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}
* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.
* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."
* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible

material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $- C\,H_2 - + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2\,H_3\,Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2\,H_3\,Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\,H_2O + 0.5\,N_2 + 1.25\,O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a\,H_b\,O_c\,F_e + (a+b/4-c/2-e/4)\,O_2 + (n+1/2)*e*(1-x) - b/2)\,H_2O = (a-ex/4)\,CO_2 + + ex/4\,CF_4 + e(1-x)\,(HF) + e(1-x)\,n\,H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

16- 237 - (Table 770-53): Reject
SUBMITTER: Irving Mande, Edwards System Technology (EST)
COMMENT ON PROPOSAL NO: 16-178
RECOMMENDATION: Reconsider the panel action and accept this proposal.
SUBSTANTIATION: The panel statement does not seem to consider that OFC type could also be specified for safety reasons. The panel should explain why they do not consider metallic strength members and metallic armor or sheath to be usable for safety reasons.
PANEL ACTION: Reject.
PANEL STATEMENT: Article 770 permits nonconductive optical fiber cable, under some conditions, to be run in the same raceway with power cable. Conductive optical fiber cable is never permitted to run in the same raceway with power cable because of the possibility of energizing the metallic strength member. The cable substitution table and chart consider fire performance and shock hazard. Mechanical protection is not considered in Article 770. The substitution table does not consider engineering considerations.

(Log #301)

16- 245 - (800-2 Abandoned Cable (New)): Accept in Principle
SUBMITTER: Gerald Lee Dorna, Belden Wire & Cable Co.
COMMENT ON PROPOSAL NO: 16-189
RECOMMENDATION: The definition of "Abandoned Cable" should be the same here as what we accepted in Proposal 16-273. It should be:
"Cable that is neither terminated at ~~both ends, at a connector or other~~ equipment, not identified for future use with a tag."
This is the same wording we accepted for Proposal 16-273.
SUBSTANTIATION: The reason we took out the reference to connectors in Proposal 16-273 is because CATV cable usually has connectors attached. It was our concern that CATV cables would have connectors attached and then would not fall under the definition the panel had accepted in principal. If we make the definition the same as I have suggested above then it will make it irrelevant on whether the cable has connectors or not. I can foresee someone using the fact that the cable has a connector on it, therefore it does not fall under "abandoned cable" and does not need to be removed.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-247.

ARTICLE 800 —COMMUNICATIONS CIRCUITS

(Log #459)

16- 246 - (800-2, Abandoned Cable): Accept in Principle in Part
SUBMITTER: Technical Correlating Committee on Signaling Systems for the Protection of Life and Property
COMMENT ON PROPOSAL NO: 16-189
RECOMMENDATION: Revise the proposed definition of abandoned cable to read as follows:
"Cable that is neither terminated at equipment, nor identified for future use with a dated tag."
SUBSTANTIATION: The definition proposed for 820-2 by the Panel Action of Proposal 16-273 is clear and concise and should be used consistently in all Articles. This proposed definition has been modified in the above recommendation to add the word "dated" before the word "tag." The tag should be dated so the authority having jurisdiction can determine the date on which the cable was designated for future use. This will establish a means to allow the decision of abandonment to be re-evaluated periodically if the authority having jurisdiction so desires.
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: See panel action and statement on Comment 16-247. That comment included a definition. The part adding the word "dated" is rejected.
In buildings that are prewired for communications, cables may remain unused for extended periods until tenants change and require a reconfiguration of communications cabling. To add a date to the tag would add confusion, and might even result in removal of cable that is part of the intended building prewiring. The Manual of Style precludes the use of requirements within definitions.

(Log #1848)

16- 247 - (800-2): Accept in Principle
SUBMITTER: Robert W. Jensen, dbi-Telecommunications Infrastructure Design
COMMENT ON PROPOSAL NO: 16-189
RECOMMENDATION: New wording:
Abandoned Cable. Installed cable that is neither terminated at both ends at a connector or other equipment, nor identified for future use with a tag.
SUBSTANTIATION: BICSI added the word installed to show that the cable needs to be installed and not in the installers truck. We retained "terminated at both ends" because communications cable is typically terminated at both ends when it is in use (i.e., when not abandoned).
PANEL ACTION: Accept in Principle.
Revise the recommendation to read as follows:
"Abandoned Communications Cable. Installed communications cable that is not terminated at both ends at a connector or other equipment and not identified for future use with a tag."
PANEL STATEMENT: The revised text satisfies the submitter's intent and more clearly expresses the definition and complies with the Manual of Style.

16- 249 - (800-2-Abandoned Cable): Accept in Principle
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-189
RECOMMENDATION: Revise text to read as follows:
Abandoned Cable: Cable that is <u>not</u> ~~neither~~ terminated at both ends, ~~at a connector or other~~ <u>not connected to</u> equipment, <u>or not</u> ~~nor~~ identified for future use with a tag.
SUBSTANTIATION: The term "terminated at a connector" may result in cables being left in place as many cables come with connectors or the installer could add crimp connectors and leave the cables in place. The present language can be easily misunderstood: does the cable have to be terminated and tagged, or is it a choice?
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-247.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21

16- 253 - (800-5): Reject
SUBMITTER: Glenn W. Zieseniss, Crown Point, IN
COMMENT ON PROPOSAL NO: 16-192
RECOMMENDATION: Change the "Accept in Principle" to "Reject".
SUBSTANTIATION: I agree with Mr. Egesdal's and Mr. Speer's negative vote and comment on Proposal 16-192. This proposal is giving a "blanket okay for any type of ceiling tile to support the possible added weight of 3 cables of less than 1/2 in. in diameter on each ceiling tile. The proposal does not affirm that the ceiling tile industry was contacted of adding weight to lay on their product. This product is not part of the building structure, and is not designed to be suitable for supporting cables. I have seen ceiling tiles which look as if made of fiber glass insulation which has a finished surface on the exposed side of the ceiling. It is my belief that this ceiling tile would not accept additional weight upon it. I have contacted three ceiling tile companies or organizations on this proposal. They all suggested that their ceiling tiles are not to support additional weight. I have provided copies of my e-mail contacts.
NOTE: Supporting Material is available at NFPA Headquarters.
PANEL ACTION: Reject.
PANEL STATEMENT: The recommendation of Comment 16-270a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications cables in existing construction. The restrictions contained in Comment 16-270a limit both the number and size of wires and cables permitted on each ceiling panel, thereby controlling weight and accumulation so that cables can be easily moved aside to permit access. The submitter's concern about weight is addressed by decreasing the size of the cable to 1/4 inch and limiting the number of cables to three per each 10 ft x 10 ft area.

(Log #861)

16- 254 - (800-5): Accept in Principle in Part
SUBMITTER: Larry F. Miller, National Electrical Manufacturers Association (NEMA)
COMMENT ON PROPOSAL NO: 16-192
RECOMMENDATION: The Panel should continue to Accept the proposal in Principle but revise the Panel action text to read as follows:
800- Access to Electrical Equipment Behind panels Designed to Allow Access.
Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use or maintenance. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).
a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.
b.1. Installation of cables in suspended lay-in type ceiling spaces shall comply with 300.11.
2. Installation of cables in other than suspended lay-in type ceiling spaces shall comply with 300.11 where the space is accessible.
3. Where the ceiling is not the lay-in type, and the space is not accessible, three cables less than 13 mm (0.5 in.) shall be permitted to be installed unsupported by the building structure between access points or access panels.
~~Buildings with existing cabling systems.~~
~~Where practicable, installation of cables shall comply with Section 300.11. Where impracticable to comply with Section 300.11, cables less than 13 mm (0.5 in) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.~~
~~1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.~~
~~2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum three supported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid."~~
SUBSTANTIATION: We agree with Mr. Egedsal's and Mr. Speer's negative comments that suspended ceilings are not intended to support electrical wires or cables.
Section 300-11(a)(1) (wiring located within the cavity of a fire-rated floor-ceiling or roof-ceiling) allows an exception for wiring that has been tested as part of the fire-rated assembly. This proposal could compromise the fire-rating of the ceiling by overriding that requirement. The words "or maintenance" have been added because so much of the damage occurs in ceiling spaces as various trades perform maintenance.
The submitter states that he has submitted companion proposals for Articles 725 760, 770, 820 and 830. If each of these articles will allow three cables per ceiling tile, this could result in a total of 18 cables per ceiling tile, which appears to be approaching the "excessive accumulation" the submitter agrees could be a hazard. Limiting the size and quantity of cable permitted to be fished in non-lay-in ceiling spaces will help control the weight of cable (combined with that permitted in the other articles referenced above) on these ceilings.
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: The panel rejects the recommended addition of the word "maintenance." The term "normal building use" includes "maintenance." The balance of the recommendation is accepted in principle. Refer to the recommendation and substantiation on Comment 16-270a.

(Log #968)

16- 255 - (800-5): Accept in Part
SUBMITTER: Palmer Hickman, Royersford, PA
COMMENT ON PROPOSAL NO: 16-192
RECOMMENDATION: Reject Proposal 16-192 as amended by Code-Making Panel 16. Accept Proposal as submitted by Mr. Brunssen.
SUBSTANTIATION: I implore Code-Making Panel 16 to reconsider their action on this proposal. The proposed 800.5(B)(2) would now permit three cables to be installed on the tiles of a suspended ceiling, without providing any technical substantiation for this allowance.

I understand that this proposed allowance of ceiling support only applies to buildings with existing cabling systems where it is "impracticable" to comply with 300-11. Impracticability does not provide technical substantiation to allow a ceiling assembly that has not been evaluated to support the potential additional load of three cables on each and every ceiling tile.

I am aware that Chapter 8 is independent of other chapters except where specifically referenced therein. Panel 16 has referenced 300-11, and Code-Making Panel 3 is on record reaffirming their prohibition of ceiling assemblies being used beyond the manufacturers design parameters in the Panel Statement to Comments 3-53 and 3-57 of the 1998 ROC, and Proposal 3-68 of the 2001 ROP. In the latter reference, Code-Making Panel 3 states: "The panel reaffirms its position that an independent means of support shall be provided for all wiring, not just branch circuit wiring...".

The substantiation provided by Mr. Brunssen for his proposal does not support the proposed change as amended by Code-Making Panel 16. He claims that "a limited amount of wiring or cabling laid directly on a suspended ceiling is permitted..." without stating where this permission is given. The entire substantiation of the submitter seems contrary to the action of the panel. I am not sure he would recognize the end result as the proposal he made. Mr. Brunssen begins his substantiation by stating that "Section 800-5 may be misinterpreted to mean that wires and cables may not be placed directly on suspended ceilings." He notes that the 1999 NEC Handbook "Figures 800-1 and 800-2 lead the reader to conclude that no wires or cables are permitted to rest directly on the suspended ceiling." The submitter also stated Code-Making Panel 16 responded to a proposal to Article 725 (1992 TCD Comment 16-18) that the proposed requirement "...would still allow some cabling of a limited quantity above the ceiling tile, but not to an excessive amount." Note the words "above the ceiling tile", not on the ceiling tile. I feel these examples are not misinterpretations, but rather correct interpretations, and a case to reject this proposal as amended by CMP16.

In conclusion, I respectfully disagree with the Panel Action on this Proposal. I find no technical substantiation to warrant such a dramatic change. Mr. Brunssen presented a well-researched proposal addressing access, not support. The substantiation of the submitter does not support this change, nor does the Panel Statement.
PANEL ACTION: Accept in Part.
PANEL STATEMENT: The panel accepts the portion of the comment to retain Section 800.5, and rejects the portion of the comment to reject Proposal 16-192. Refer to the recommendation and substantiation on Comment 16-270a. Also refer to the panel action and statement on Comment 16-253.

(Log #1147)

16- 256 - (800-5): Accept in Principle
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-192
RECOMMENDATION: Revise as follows:

800-5. Access to Electrical Equipment Behind Panels Designed to Allow Access. Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.

b. Buildings with existing cabling systems. Where practicable, installation of cables shall comply with Section 300-11. Where impracticable to comply with Section 300-11, cables less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.

1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.

2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of ~~any one~~ each ceiling tile, i.e., up to three wires and cables are permitted to lay on a ceiling tile. The cables shall be run parallel to the ceiling grid.

SUBSTANTIATION: Proposed Section 800-5(b)(2), as presently written in Proposal 16-192, panel action, is confusing and could be interpreted as permitting a total of only three unsupported wires and cables above a suspended ceiling. The intent of the panel was that up to a maximum of three unsupported wires and cables may be routed across each and every ceiling tile. The revision proposed in this comment clarifies and accomplishes the intent of the panel. This is a companion comment and is intended to correlate with comments on Proposals 16-38, 16-112, 16-159, 16-276, and 16-332.
PANEL ACTION: Accept in Principle.

16- 257 - (800-5): Accept in Principle
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-192
RECOMMENDATION: Continue to accept in principle.
SUBSTANTIATION: Panel 16 should continue to accept in principle as it provides a reasonable and safe solution to placing a limited number of signaling and communications wires and cables in existing construction. The restrictions contained in the proposed change limit both the number and size of wires and cables permitted on each suspended ceiling panel. In this manner additional weight, as well as an accumulation of wires and cables that would otherwise restrict access above suspended ceiling panels, is controlled and limited. The limited number of cables permitted can easily be moved aside to permit access. Some concern has also been expressed that cables placed directly on the ceiling panels would degrade the fire rating of the ceiling. The suspended ceiling, part of a membrane that is intended to retard fire from spreading into the ceiling cavity, would be unaffected in its ability to retard the spread of fire by a limited number of wires and cables resting on top of the panels. This is a companion comment and is intended to correlate with comments on Proposals 16-38, 16-112, 16-159, 16-276, and 16-332.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to the substantiation on Comment 16-270a. This action meets the intent of the submitter.

(Log #1166)

16- 258 - (800-5): Accept in Principle
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-192
RECOMMENDATION: Revise as follows:

800-5. Access to Electrical Equipment Behind Panels Designed to Allow Access. Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.

b. Buildings with existing cabling systems. ~~Where practicable, installation of cables shall comply with Section 300-11. Where impracticable with Section 300-11, c~~Cables less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.

1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.

2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.

Where the maximum number of cables permitted in 1 or 2 will be exceeded, installation of cables shall comply with Section 300.11.

SUBSTANTIATION: The Technical Correlating Committee has directed that Proposal 16-192 be revised to comply with the NEC Style Manual 3.2.1 relative to the use of unenforceable terms. The proposed revision contained in this comment removes the unenforceable terms "practicable" and "impracticable"; the remaining text is in agreement with the NEC Style Manual 3.1.2 using the phrase "shall be permitted" to indicate allowed optional or alternate methods. The added text (final sentence) provides direction on how to proceed if the limits of 800-5(b)(1) or (2) will be exceeded. This is a companion comment and is intended to correlate with comments on Proposals16-38, 16-112, 16-159, 16-276, and 16-332.

PANEL ACTION: Accept in Principle.

16- 259 - (800-5): Accept in Principle

SUBMITTER: Thomas J. Garvey, Milwaukee, WI

COMMENT ON PROPOSAL NO: 16-192

RECOMMENDATION: Revise 800-5 to read as follows:

"800-5. Access to Electrical Equipment Behind Panels Designed to Allow Access. Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with 300-11.

SUBSTANTIATION: The proposed text for existing buildings is not enforceable. For example, a 20 foot by 64 foot room with lay-in type tiles. Not including any lay-in luminaires, there would be 100 4-foot by 2-foot tiles. How many cables would be permitted in this room supported by the tiles? 30? 48? Now the owner replaces the ceiling with 2-foot by 2-foot tiles. How many cables are now permitted?

Ceiling systems are not an acceptable substitute for proper cable support.

PANEL ACTION: Accept in Principle.

PANEL STATEMENT: Refer to the recommendation and substantiation of Comment 16-270a which limits the number of unsupported cables that can be installed in non-fire rated ceilings. Installations in fire-rated ceilings must comply with Section 300.11.

(Log #CC1605)

16- 270a - (800-5, 7, 8): Accept

Note: The Technical Correlating Committee directs that the references to Articles 640 and 650 be deleted because the panel did not accept similar requirements in those articles. The Technical Correlating Committee also directs that the FPN which contains a mandatory requirement be deleted to comply with the NEC Style Manual.

SUBMITTER: CMP 16

COMMENT ON PROPOSAL NO: 16-192

RECOMMENDATION: Renumber current Section 800-7 as 800-8.

Retain the existing 1999 code text for Section 800-5 (unmodified).

Add new Section 800.7 to read as follows:

800.7 Installation of Circuits.

Communications circuits shall be installed in compliance with A or B.

A. New Ceiling Construction. The installation of cables in new ceiling construction shall comply with Section 300-11.

B. Existing Ceilings.

1. Fire-Rated Ceilings. The installation of cables in the cavity of an existing fire-rated ceiling assembly shall comply with Section 300-11.

2. Non-Fire-Rated Ceilings. For installations in the cavity of an existing non-fire-rated ceiling assembly, cables less than 6 mm (0.25 in) in diameter shall be permitted to be installed unsupported from the building structure in accordance with the following:

a. Fixed or Hard Ceilings. In areas having fixed or hard ceilings with access points or access panels, a combined total of three cables from Articles 640, 650, 725, 760, 770, 800, 820 and 830, shall be permitted to be placed between access points or access panels in the ceiling. Additional cables shall be installed in accordance with 300.11.

b. Suspended Lay-In Ceilings. In areas having suspended lay-in ceilings, in any 3 m by 3m (10 ft. x 10 ft) ceiling area, a combined total of three cables from Articles 640, 650, 725, 760, 770, 800, 820 and 830, shall be permitted to be installed directly on the ceiling grid. Additional cables shall be installed in accordance with 300.11.

FPN. Cables of all types are included in the total limit of three cables, not three cables from each article.

SUBSTANTIATION: Proposal 16-192 was accepted in principle to permit the installation of unsupported cables under limited conditions. Proposal 16-192 text, however, was too broad and unclear. The text of this comment clarifies the original intent. The new text includes requirements to comply with Section 300.11. Permitted installation conditions will not compromise the integrity of fire-rated ceilings. For non-fire-rated ceilings, the permitted relief from Section 300.11 is limited to very specific conditions. Section 800.5 is not being modified because the accessibility requirements should remain.

The sections have been renumbered so that they appear in a logical order.

PANEL ACTION: Accept.

COMMENT ON PROPOSAL NO: 16-192
RECOMMENDATION: Reject this proposal.
SUBSTANTIATION: This proposal will allow for a continuous buildup of cable, lying on ceilings without individual support, creating a dangerous situation. All cable, of any type system must be supported independently of the ceiling system.
Ceiling systems are not designed to support additional weight from cables or raceways of any type. Cable support is a Safety issue. Persons who maintain systems will constantly fight with cable which may impede access to most ceiling tiles. An accessible ceiling must remain "Accessible." The intent of many safety driven sections in the NEC is to support/secure all cables and raceways to the structural ceiling. This prevents the buildup of cable from contributing to a ceiling failure. This also assures that in the event of a ceiling failure cables and raceways from all types of systems remain supported by the building structure.
If this proposal is accepted, in a fire situation, the failure of the ceiling system would result in a tremendously dangerous situation for fire fighters and rescue personnel.
Individual support of cable will not create a tremendous expense for the user. There are many readily available support systems including cable tray to allow for the safe installation of system cables.
This comment represents the official position of the International Brotherhood of Electrical Workers Codes & Standards Committee.
PANEL ACTION: Reject.
PANEL STATEMENT: The submitter's concern regarding accessibility is addressed by retaining the original Section 800.5. The recommendation of Comment 16-270a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications cables in existing construction. The restrictions contained in Comment 16-270a limit both the number and size of wires and cables permitted on each ceiling panel, thereby controlling weight and accumulation so that cables can be easily moved aside to permit access. The submitter's concern about weight is addressed by decreasing the size of the cable to 1/4 inch and limiting the number of cables to three per each 10 ft x 10 ft area.

16- 263 - (800-5): Accept in Principle
SUBMITTER: Thomas J. Garvey, Milwaukee, WI
COMMENT ON PROPOSAL NO: 16-192
RECOMMENDATION: Revise 800-5 to read as follows:
800-5. Access to Electrical Equipment Behind Panels Designed to Allow Access. Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply Section with 300-11.
SUBSTANTIATION: The proposed text for existing buildings is not enforceable. For example, a 20 foot by 64 foot room with lay-in type tiles. Not including any lay-in luminaries, there would be 100 4 foot by 2 foot tiles. How many cables would be permitted in this room supported by the tiles? 30? 48? Now the owner replaces the ceiling with 2 foot by 2 foot tiles. How many cables are now permitted?
Ceiling systems are not an acceptable substitute for proper cable support.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-259.

16- 264 - (800-5): Reject
SUBMITTER: Christopher R. Pharo, Marlton, NJ
COMMENT ON PROPOSAL NO: 16-192
RECOMMENDATION: I ask that this proposal be rejected.
SUBSTANTIATION: This proposal seems to conflict with the requirements in 800-6 that requires support every 5 feet.
A suspended ceiling system is not recognized in other areas of the Code to support cables, conduit, or boxes. Special attention has been given to this in past code cycles. We finally have a consensus of what is good for the industry, now we are being asked to take a step backwards.
PANEL ACTION: Reject.
PANEL STATEMENT: Refer to the recommendation and substantiation of Comment 16-270a which addresses the concerns of accessibility, weight and support.

(Log #743)

16- 265 - (800-5(b)): Accept in Principle in Part
SUBMITTER: Richard P. Owen, City of St. Paul, Electrical Inspection
COMMENT ON PROPOSAL NO: 16-192
RECOMMENDATION: Replace (b) of the proposal with the following text:
(b) Buildings not Covered Under (a) Above. In areas having ceilings with access points or panels and having 900 mm (3 ft) or less vertical clearance above the ceiling, it shall be permissible to fish a maximum of 3 cables, each less than 13 mm (0.5 in.) in diameter, between access points in the ceiling.
SUBSTANTIATION: The Technical Correlating Committee directed Panel 3 Chair Raymond Weber to form a Task Group to review these proposals and to submit the results as comments to Panel 16. Task Group 3-16, consisting of Chair Weber, members Steven Speer; Lee Hewitt; Richard Owen and Ron Maassen held a conference call on October 3, 2000 and developed the above language as a comment. The Task Group was concerned with allowing unsupported cabling above suspended ceilings, since companion proposals for Articles 725, 760, 770, 800, 820 and 830 would also allow this limited cabling without support. The possible accumulation of cable allowed by all these articles would be excessive and would both limit access to a ceiling and conflict with Section 300.11. Rewording of (b) also eliminated the unenforceable terms "practicable" and "impracticable" as directed by the Technical Correlating Committee.
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: The panel rejects the specific limitations in the comment but accepts the principle of permitting a limited number of cables. The recommendation of Comment 16-270a provides a reasonable, safe, and practical solution to placing a limited number of unsupported communications wires and cables in existing construction.

(Log #1257)

16- 266 - (800-5(b)(2)): Reject
SUBMITTER: J. Paul Spinn, USG Research & Technology Center
COMMENT ON PROPOSAL NO: 16-192
RECOMMENDATION: Delete the following text:
In areas having suspended lay in ceiling, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.

SUBSTANTIATION: By allowing a maximum of three unsupported cables on top of any one (or more) ceiling tiles, the fire-rating of the assembly and the Class A surface burning characteristic requirement, which includes flame spread and smoke development, could be jeopardized. By decreasing the fire-rating of the plenum assembly and the surface burning characteristic of the ceiling tile, the life safety of the occupants can be negatively affected. By rejecting this proposal, these problems can be eliminated.

To substantiate the comment made for the proposal, four key points are provided:

[1] For a fire rated floor/ceiling or roof/ceiling assembly, placement of unsupported cables on top of any one ceiling tile or a row of ceiling tiles could invalidate the fire-rating for a particular assembly. The rationale for this argument are:
(a) The weight of the cables could cause premature tile fallout leading to an early failure of the assembly, which is tested in accordance with NFPA 251 or ASTM E 119.
(b) The increased heat of combustion associated with the cable jackets, which commonly use plastics, will add to the total fire load of an assembly. As the total fire load increases for an assembly, the fire endurance of the assembly will decrease, which could jeopardize an assembly's fire-rating.

[2] For a Class A ceiling, placement of unsupported cables on the ceiling can effect flame spread and smoke development performance and jeopardize the required Class A rating for the ceiling tiles. The rationale for this argument are:
(a) The flame spread will increase due to the increased total heat load, which is caused by the plastic on the cable jacket.
(b) The smoke development will increase due to the cable jackets, which are usually plastic such as PVC or CPVC.

[3] The placement of unsupported cables on top of any one or more ceiling tiles presents potential life safety issues for occupants due to the decreased fire-rating of the floor/ceiling or roof/ceiling or an increase in the ceiling surface burning characteristics.

[4] Placement of unsupported cables on top of any one ceiling tile or a row of ceiling tiles would increase ceiling tile sag due to increased weight of the cables on the ceiling tiles, and would impair the accessibility of the ceiling plenum.

PANEL ACTION: Reject.
PANEL STATEMENT: The recommendation of Comment 16-270a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications cables in existing construction. The restrictions contained in Comment 16-270a limit both the number and size of cables permitted on each ceiling panel, thereby controlling weight and accumulation so that cables can be easily moved aside to permit access. The submitter's concern about weight is addressed by decreasing the size of the cable to 1/4 inch and limiting the number of cables to three per each 10 ft x 10 ft area. The revised text precludes the installation of cables in all fire-rated ceiling assemblies.

(Log #2086)

16- 267 - (800-5(b)(2) (New)): Accept in Principle in Part
SUBMITTER: Marcelo M. Hirschler, GBH International
COMMENT ON PROPOSAL NO: 16-192
RECOMMENDATION: Revise text as follows:

800-5. Access to Electrical Equipment Behind Panels Designed to Allow Access

Access to equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).

a. New building construction (e.g. renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.

b. Buildings with existing cable systems. Where practicable, installation of cables shall comply with Section 300.11. Where impracticable to comply with Section 300.11, in those areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables less than 13 mm (0.5 in) in diameter, between access points in the ceiling. ~~cables less than 13 mm (0.5 in) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.~~

~~1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.~~

~~2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.~~

SUBSTANTIATION: The permission granted by the panel to install cables on suspended ceiling tiles should be rescinded. Neither cables nor any other item should be installed on top of a suspended ceiling tile. The support systems of suspended ceilings are not designed to resist any significant amount of weight without being deflected or broken.

This issue has been raised on Proposal 16-192 (log 1665) in negative comments by two panel members, Mr Egesdal and Mr Speer, who both correctly point out that suspended ceiling tiles are not intended to support the weight of electrical cables. Mr. Sandy Egesdal repeats his negative comment on this proposal.

The point made by the Technical Correlating Committee on proposal 16-38 that such use would constitute an exposed use of cables is an additional consideration to rejecting this part of the proposal.

PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: The panel accepts the principle of permitting a limited number of cables to be installed in a fixed or hard ceiling. The panel rejects the balance of the submitter's recommendation including the limiting of the installation of cables in a suspended lay-in ceiling . The recommendation of Comment 16-270a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications cables in existing construction.

COMMENT ON PROPOSAL NO: 16-192a
RECOMMENDATION: Delete 800-6 and incorporate the information in 800-5 as follows:

800-5. ~~Access to Electrical Equipment Behind Panels Designed to Allow Access~~ Mechanical Execution of Work. Communications circuits and equipment shall be installed in a neat and workmanlike manner. Access to electrical equipment shall not be denied by an accumulation of ~~wires and~~ cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. ~~Access to electrical equipment behind ceilings designed to allow access.~~ Cables installed exposed shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11 Cables shall be supported by structural components of the

building. Such cables shall be attached to structural components at intervals not exceeding 1.52 m (5 ft) and within 305 mm (12 in.) from every cabinet, box or fitting by straps, staples, hangers or similar fittings designed and installed so as not to damage the cable. The installation shall also conform with Section 300-4(d).

(b) Buildings with existing cable systems. Where practicable, installation of cables shall comply with ~~Section 300-11~~ 800-5(a). Where impracticable to comply with ~~Section 300-11~~ 800-5(a), cables less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.

1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.

2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.

Continue to delete the fine print note as proposed in Proposal 16-192a.

SUBSTANTIATION: This is a companion comment and is intended to correlate with similar comments on Proposals 16-39, 16-115, 16-159a, 16-276a, and 16-333a. Sections 800-5 and 800-6 actually address the same issue, the mechanical execution of work. Accessibility behind panels designed to allow access is really an "execution of work" issue. Additionally, the Technical Correlating Committee has identified a potential conflict between the panel action on Proposals 16-38 and 16-39, that would also result here in 800. This comment editorially combines 800-5 and 800-6 into a single Section 800-5 requiring attachment to the building structure of exposed cables and conductors and, where impracticable to do so, permits a limited number of cables of specified maximum size to be placed on suspended ceiling tiles. It accommodates the intent of both proposals that cables should be supported by the building structure, but in extenuating circumstances in existing construction, a limited number and weight of cables may be placed on a suspended ceiling. Further, in the first paragraph of 800-5, the phrase "wires and" is deleted as communications circuits are typically provided via cable and cable is defined in 800-2.

PANEL ACTION: Reject.

PANEL STATEMENT: The sections should not be combined. Refer to the recommendation and substantiation for Comment 16-270a where these recommendations are addressed.

16- 271 - (800-10(c)): Accept in Principle

SUBMITTER: Steven C. Johnson, Time Warner Cable

COMMENT ON PROPOSAL NO: 16-202

RECOMMENDATION: Reject the proposal to prohibit use of service masts for drop attachments.

SUBSTANTIATION: There is no reason to force a homeowner to install a separate mast to accommodate communications (telephone, CATV) service drops wherever the service mast can be listed to do so. An arbitrary prohibition of attaching to electrical masts is not reasonable. Where the mast can be shown to support additional attachments without creating a safety hazard, these attachments should be allowed. Reasonable qualifications would include the ability to support the weight (with ice loading) and not damage the mast or structure, ability to maintain proper clearance, etc.

PANEL ACTION: Accept in Principle.

PANEL STATEMENT: Refer to the panel action and statement on Comment 16-272.

NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21

VOTE ON PANEL ACTION:

AFFIRMATIVE: 16

NEGATIVE: 5

EXPLANATION OF NEGATIVE:

DORNA: I am in agreement with Mr. Kahn that the primary jurisdiction of these items are in Code-Making Panel 4. Code-Making Panel 4 has rejected the idea, and I believe Code-Making Panel 16 should do the same. Therefore, I am changing my vote to negative.

KAHN: The comments should be rejected and the original Panel Action to Reject Proposal 16-202 should be sustained.

Code-Making Panel 4 has rejected the Proposal and that panel has primary jurisdiction. In their Panel Statement, they state: "... that they do not believe that the listing of the product will adequately address the personnel issues that are created by the co-mingling of the different systems on a common mast. Issues such as loading can be addressed by the proposed listing, however personnel safety cannot be assured regardless of the listing criteria." I agree with their assessment.

A task group of Code-Making Panel 4 and Code-Making Panel 16 members as suggested in the Panel Statement should be formed to study the problem further if the
Technical Correlating Committee deems it advisable.

MANGAN: I am voting against Panel 16's action on Comments 16-271; 16-272; 16-273 on Section 800.10, Comments 16-336; 16-337; 16-338 on Section 820.10, Comments 16-391; 16-392; 16-393 on Section 830.10. The addition of these 3 cables to an electric service mast would compromise the safety of workers and the added liability of these cables in close proximity to live conductors. This type of installation would be a violation of Sections 230.28 and 300.11. The electric utility companies would not allow any other drops to this service mast. Also, service masts are not limited to single family homes, they are also used on service stations and low commercial buildings. The requirements for electric service masts are designated by the electric utility company serving the area.

SPEER: Code-Making Panel 4 has jurisdiction over this issue and any proposed change should be addressed to that panel.

In Comment 16-272, the submitter states that it is "unreasonable to arbitrarily prohibit attaching to the electric service mast", thereby causing the homeowner to bear the cost of a separate comunications mast.

The reasoning for not allowing other systems to attach drops to the electric service mast is not "arbitrary", but a well founded safety concern for those who must have access to the mast area. They may be required to work with energized circuits associated with that mast.

The required safe working clearances may also be impeded by the installation of other systems on the electric service mast, as well as, the safe avenues of escape from the area may become unnecessarily restricted, for those required to work on energized circuits associated with these masts.

Further, the submitter suggests that the homeowner might suffer less expense by utilizing a single mast "listed" for the application, as opposed to using separate system masts. My experience suggests that the expense for a "listed" piece of equipment will far exceed the cost of a piece of galvanized rigid conduit or intermediate rigid conduit, as is now being used.

TODD: See my explanation of negative on Comment 16-155.

(Log #1144)

16- 272 - (800-10(c) (New)):

Note: The Technical Correlating Committee directs that this comment be reported as "Reject" to correlate with the action on Proposal 4-73 and Comment 4-51.

SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-202
RECOMMENDATION: Accept the proposal.
SUBSTANTIATION: This is a companion comment to my comment on Proposal 4-73 wherein it was proposed to revise Section 230-28 to permit communications wires and cables to be attached to a service mast that is listed for the purpose. Code-Making Panel 4 has been asked to reconsider their rejection of Proposal 4-73, based on the panel statement that Code-Making Panel 4 does not "believe" listing will adequately address the personnel safety issues. Code-Making Panel 4's position is contrary to both the industry and NEC accepted method to ensure the safety of wiring, cable, and equipment when used for its intended application, that of listing by a Nationally Recognized Testing Laboratory (NRTL). Listing will ensure that the service mast can adequately support multiple attachments while providing for the safety of power, communications and CATV technitions who must access the service mast. Code-Making Panel 16 stated that detailed design and installation requirements are not defined. This is the purpose of listing - to establish that a product will be safe when used as intended. It is unreasonable to arbitrarily prohibit attaching to the electric service mast and cause the homeowner to bear the cost of a separate mast for communications. When the mast is listed and installed properly for its intended use it will be capable of safely supporting, and safely permitting access to, multiple attachments. CMP 16 should accept Proposal 16-202 based on the merits of the submitter's original substantiation, contingent upon the action of Code-Making Panel 4.

Note also companion comments to Proposals 16-281 and 16-344.

PANEL ACTION: Accept.
PANEL STATEMENT: CMP 16 understands that CMP 4 has primary jurisdiction over requirements associated with the power service mast. A companion comment has been submitted to CMP 4 to allow relief for the attachment of communications cables to the power service mast. Should CMP 4 continue to reject the proposal, CMP 16 requests that the Technical Correlating Committee assign a task group consisting of members of both panels to review the issues.

(Log #1118)

16- 274 - (800-40(a)(4)): Reject
SUBMITTER: Steven C. Johnson, Time Warner Cable
COMMENT ON PROPOSAL NO: 16-212
RECOMMENDATION: Reject Proposal 16-212.
SUBSTANTIATION: 1. The distance between entrances for different services is practically limited to 100 feet for most installations which corresponds to 0.3 ohms for 14 AWG solid copper conductor and 0.05 ohms for 6 AWG solid copper conductor. Neither resistance is significant. The new 800-40(a)(4) proposed would mandate placing an additional electrode wherever the distance between the grounding terminal for communications cables and the electrical service ground is greater than 20 feet. The additional electrode would not significantly decrease resistance to ground nor increase safety.

2. The practical difference between the existing code and the proposed change is that the grounding conductor size is increased to 6 AWG every time the 20-foot distance rule is violated. This difference results in 0.25 ohm difference in the extreme case of 100 feet grounding conductor run. The difference is usually significantly less than 0.25 ohms since the distance is usually less than 100 feet.

3. The proposal provided no technical justification for the quantified 20 foot limitation and no demonstrated improvement in safety. No problems are cited and no incidents of damage or harm are presented that are the result of present installation and bonding practices.

4. The 20 foot rule is not always practical to maintain. The new proposal would result in a backlash from homeowners whenever an additional electrode is to be placed and 6 AWG wire to be used to bond it to the existing electrode system.

PANEL ACTION: Reject.
PANEL STATEMENT: The panel's intent is to limit the potential difference between power and communications circuits during lightning events.

That potential difference is generally a function of conductor inductance (L), which increases in direct proportion to conductor length, and the rate of rise of the current (di/dt). This proposal addresses that issue, encourages short primary protector grounding conductor, provides guidance as to a reasonable maximum length, and provides an alternative where it is not practicable to meet the maximum length (20 ft) restriction. The proposed length restriction is limited to one- and two-family residences as it is such installations that are more likely to have diverse power and communications entrances and experience lightning-related problems (urban/suburban environment with a fewer elevated structures and extensive buried metallic objects).
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:
AFFIRMATIVE: 19
NEGATIVE: 2
EXPLANATION OF NEGATIVE:
JOHNSON: This proposal has no technical merit and no demonstrated improvement in safety. To my knowledge, no incidents of harm or damage that were the result of existing installation and bonding practices have been documented to support such a change in existing practice.

The practice within the cable industry is to maintain grounding conductors as short as practicable. In many installations, the distance between entrances for different services can be limited to less than 20 feet. Where this cannot be reasonably accomplished, typical worst-case grounding conductor installations are under approximately 100 feet. This distance corresponds to 0.3 ohms for 14 AWG solid copper conductor and 0.05 ohms for 6 AWG solid copper conductor. Neither resistance is significant. Notwithstanding the additional increase in installation cost to the customer, the 20 ft rule cannot be practically maintained, and would result in a negative reaction from homeowners whenever an additional electrode is to be placed and 6 AWG wire to be used to bond it to the existing electrode system.

Justification for introduction of the new rule was based solely on the danger caused by lightning impulses present in the telecommunications drops. Previous comments to the proposal clearly indicated that a direct contact with high voltage power lines

is addressed adequately by the existing NEC rules and together with NESC rules provides for a safe installation.

The telecommunications installation cannot be considered separately from the rules imposed by the rules of NESC. The NESC requires a minimum of four (4) grounding/bonding points in each mile of plant. The impedance of these grounding points is much lower than the impedance of the grounding points at the cable entrance to the building (considering communications drops and grounding conductors). This is true for any type of current surges and their rise times, ranging from 60Hz current (resulting from contacts with power lines) to lightning induced surges of a 4 microsecond rise time.

Previous editions of the NEC allowed that the system contained within a block may be considered as not exposed to lightning or accidental contacts with high voltage power lines and hence did not have to be grounded at the building entrance. The new proposal approved by the panel to require point of entrance or attachment grounding in all instances was justified not by safety requirements but by the need to reduce confusion as to when grounding is or is not required. Hence, the grounding system for the communications drop at the building entrance contributes only minimally (due to its higher impedance that the grounding of the plant) in dissipation of the current surges to the ground. In the worst case, it is only one of the five grounding points for a plant within a block.

Because of the role of the entire grounding network, the increased building grounding requirement improves the ground impedance for high frequency events (similar to surges with a 4 microsecond rise time) by 20 percent at worst and by 40 percent at best. This fact, considered jointly with the points above, indicates that the total improvement provided by the new proposal is not material. No documentation has been submitted to show that the communications installations following the existing rules of the NESC and the NEC are unsafe.

TODD: The submitter of the proposal did not provide technical justification for the 20 foot limitation, originally requested for five feet, or if it solves the concerns of the proposals and comments expressed during the 1999 Code cycle. This is an additional cost to the homeowner/commercial establishment without evidence being provided that safety will be improved.

(Log #1647)

16- 275 - (800-40(a)(4)): Reject
SUBMITTER: Andy Scott, National Cable Television Association
COMMENT ON PROPOSAL NO: 16-212
RECOMMENDATION: Reject Proposal 16-212.
SUBSTANTIATION: The Cable Television industry urges the NFPA to reject this proposal. These proposals have no technical merit and no demonstrated improvement in safety. To our knowledge, no incidents of harm or damage that were the result of existing installation and bonding practices have been documented to support such a change in existing practice.

The practice within the cable industry is to maintain grounding conductors as short as practicable. In the majority of installations, the distance between entrances for different services is limited to approximately 100 ft. This distance corresponds to 0.3 ohms for 14 AWG solid copper conductor and 0.05 ohms for 6 AWG solid copper conductor. Neither resistance is significant. Notwithstanding the additional increase in installation cost to the customer, the 20 ft rule cannot be practically maintained, and would result in a negative reaction from homeowners whenever an additional electrode is to be placed and 6 AWG wire to be used to bond it to the existing electrode system.
PANEL ACTION: Reject.
PANEL STATEMENT: Refer to the panel action and statement on Comment 16-274.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:
AFFIRMATIVE: 19
NEGATIVE: 2
EXPLANATION OF NEGATIVE:
JOHNSON: See my explanation of negative vote on Comment 16-274.
TODD: See my Explanation of Negative on Comment 16-274.

(Log #2249)

16- 276 - (800-48): Reject
SUBMITTER: Guy R. Franks, SBC
COMMENT ON PROPOSAL NO: 16-220
RECOMMENDATION: Reject the proposal.
SUBSTANTIATION: Raceways for communications wires and cables have not been required to be grounded by the NEC and this has not resulted in any adverse operational or safety related issues. The rationale for this proposal does not present any technical justification to now require grounding of these raceways. Further, Section 250-86 refers the reader to Section 250-112(i), Section 250-112(i) refers the reader to Article 250, Section B for the grounding requirements associated with the system of interest. Through all of this, there is no requirement to ground the raceways of communications systems. In fact, it appears the Article 250 references result in these raceways being exempt from grounding. Since this proposal does not result in a clear and enforceable requirement Code-Making Panel 16 should reject this proposal.
PANEL ACTION: Reject.
PANEL STATEMENT: The panel reaffirms the requirement for metal communications raceways to be grounded in accordance with Section 250-86. All metal raceways should be grounded because the potential exists that raceway can be energized. This proposal is clear and enforceable.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:
AFFIRMATIVE: 20
NEGATIVE: 1
EXPLANATION OF NEGATIVE:
BRUNSSEN: The original proposal (16-220) provided no technical justification other than to "...bring metal raceways and enclosures for telecommunications cabling into conformance with other sections of the Code." Neither a safety issue, nor adverse experience with ungrounded telecommunications metallic enclosures and raceways has been cited. Installations of telecommunications equipment and circuits have maintained an exemplary safety record over many decades and there has been no demonstrated reason to revise telecom installation requirements. Further, I would ask the panel to reconsider the substantiation provided with the submitter's Comment 16-276. Section 250-86 refers the reader to Section 250-112(i) which in turn refers the reader to Article 250, Section B. Article 250, Section B addresses service conductors and does not even mention communications circuits. The result is a requirement that is unclear and unenforceable. Panel 16 should, therefore, accept Comment 16-276, which will reject the original Proposal (16-220).

(Log #752)

16- 277 - (800-50, 800-51, 800-52 and 800-53): Accept in Principle in Part
SUBMITTER: Irving Mande, Edwards System Technology (EST)
COMMENT ON PROPOSAL NO: 16-223
RECOMMENDATION: Accept the original proposal after making the following revisions that are in response to questions raised in the panel statement. Instead of deleting 800-51(g), revise it to read:

(g) Multipurpose (MP) Cables. Listing of multipurpose (MP) cables shall not be permitted after July 1, 2003. Existing inventories of new and used MP cables shall be permitted to be used until the supply is exhausted.

FPN: For the permitted use of communications (CM) type cables as a multipurpose cable that can be used as a substitute for MP and other power-limited cables on power-limited circuits, see 725-61(g); 760-61(d); 800-53(f); 820-53(d); and 830-58(e).
SUBSTANTIATION: The revisions proposed in this comment address the panel's primary concern (provisions for reuse of listed MP cables) as stated in the panel statement. The panel's other concern (recoaxial MP cables) would only eliminate the substitute for coaxial FPL cables, the primary cables would still be available. There is no requirement that there must be a substitute for every cable.

The substantiation for requesting the elimination of MP cables is provided in my original proposal.
PANEL ACTION: Accept in Principle in Part.
In section 800-51(g) insert, "Until July 1, 2003, …", at the beginning of the sentence.
PANEL STATEMENT: This editorial change accomplishes the submitter's intention of eliminating the listing of multipurpose cables while at the same time it has no effect on the use and reuse of existing multipurpose cables because no changes are being made in the applications sections for multipurpose cable.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:
AFFIRMATIVE: 21

(Log #1071)

16- 278 - (Table 800-50): Reject

Note: "See Technical Correlating Committee action on Comment 16-98."

SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.

COMMENT ON PROPOSAL NO: 16-224

RECOMMENDATION: This proposal should be rejected, the references to CMP-50 and MPP-50 should be deleted from the Table 800-50 and the CMP-50 and MPP-50 classifications should not be created.

SUBSTANTIATION: The CMP-50 and MPP-50 classifications are unnecessary classification because they are not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}
* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}
* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM

E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.

* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."

* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $- C\,H_2 - + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2\,H_3\,Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2\,H_3\,Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\,H_2O + 0.5\,N_2 + 1.25\,O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a\,H_b\,O_c\,F_e + (a+b/4-c/2-e/4)\,O_2 + (n+1/2)*e*(1-x) - b/2)\,H_2O = (a-ex/4)\,CO_2 + ex/4\,CF_4 + e(1-x)\,(HF) + e(1-x)\,n\,H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

SUBMITTER: David H. Kendall, Carlon
COMMENT ON PROPOSAL NO: 16-228
RECOMMENDATION: This proposal should be accepted.
SUBSTANTIATION: This proposal was not intended to add any value to the testing for the listing agency. Instead it was to clarify to the inspectors, installers and designers that CMP cable is permitted to be installed in those air handling spaces as defined in 300-22(b) and 300-22(c). The proposed text also clarifies that CMP cable is not permitted to be used in areas as described in 300-22(a).
PANEL ACTION: Reject.
PANEL STATEMENT: The original proposal adds no additional information, either for the listing agency to determine listing requirements or for the electrical inspector to determine applicability. The authority having jurisdiction will only determine that it is listed for plenum application.

16- 287 - (800-51(h) (New)): Reject
Note: "See Technical Correlating Committee action on Comment 16-98."
SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.
COMMENT ON PROPOSAL NO: 16-232
RECOMMENDATION: This proposal should be rejected, the new section 800-51(h) should not be created and the CMP-50 and MPP-50 classifications should not be created.
SUBSTANTIATION: The CMP-50 and MPP-50 classifications are unnecessary classification because they are not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}
* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA

255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}

* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}

* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}

* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.

* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."

* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $- C\,H_2 - + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2\,H_3\,Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2\,H_3\,Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\,H_2O + 0.5\,N_2 + 1.25\,O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a\,H_b\,O_c\,F_e + (a+b/4-c/2-e/4)\,O_2 + (n+1/2)*e*(1-x) - b/2)\,H_2O = (a-ex/4)\,CO_2 + ex/4\,CF_4 + e(1-x)\,(HF) + e(1-x)\,n\,H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

COMMENT ON PROPOSAL NO: 16-232

RECOMMENDATION: Delete proposed section 880-51(h) and associated notes.

SUBSTANTIATION: The introduction of a new class of cable ("Limited Combustible Cable") is premature at this time for the following reasons:

A. The note to the definition section 725.71(B), FPN No. 1 references NFPA 90A, Standard for the Installation of Air-Conditioning and Ventilating Systems for the definition of limited combustible. That definition is as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141J/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

a. Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50;

b. Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be combustible."

This definition was established and is applied to building construction materials and not to specific wiring methods or technologies for use in buildings. NFPA 255 and NFPA 259 were never intended for the evaluation of multi-component systems such as electrical and optical cable. More current test methods (other than NFPA 255 and 259), such as NFPA 262, the cone calorimeter, etc. provide reproducible smoke obscuration, flame spread, or heat release (not heat value) information and are more appropriate for measuring the fire hazards of cable. Not all parts of this "Limited Combustible" definition have been applied to the broad scope of cables. Until this definition can be shown as appropriate for cables (attainable and reproducible) it should not be deemed credible and supported by the National Electrical Code at this time. Referencing this inappropriate definition in the National Electrical Code is misleading and bad code.

B. The note references NFPA 255 as the test standard for smoke developed index. This test is not an appropriate test for cables for the following reasons:

a. NFPA 255 has not been harmonized, as has NFPA 262. NFPA 262 has a proven record, unlike NFPA 255.

b. NFPA 255 is not reproducible, whereas NFPA 262 has been shown to be reproducible. This lack of reproducibility has been demonstrated numerous times in round-robin testing of building materials among multiple labs.

The most recent example of this reproducibility problem has been demonstrated in the Interim Report of the Fire Protection Research Foundation (FPRF) "Limited Combustible Cable" (ex. "Permanent Plenum Cable") project, dated June 2000. This report states "The flame spread and smoke measurements in NFPA 255 show good repeatability but relatively poor reproducibility, i.e., the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerable larger than the repeatability error." (Page 9, section 4.1.2). In this case, with only two laboratories participating, errors in reproducibility were in the range of 100 percent. Given that numerous fire-testing tunnels exist, the range of error can be expected to be even larger.

This test is inappropriate for cables as the cables are installed against the top of the tunnel. This orientation is not similar to normal cable installations, and cable placement on top of the wire mesh is random in the tunnel.

C. Cable installed above ceilings does not become involved in the fire until near or at flashover. At that point in the fire development, the ceiling tile is falling to expose the cable. Cables in walls or below floors are generally exposed to the fire conditions even later in the fire development. These cables do not spread flame more than 5 ft when tested in accordance with NFPA 262. The proposed restrictions on cable appear excessive based on the fire record.

D. There is not a need established (fire record or hazard analysis) for a new cable category. There are two research projects that are intended to provide information on the fire hazard of cables. The ASHRAE project has not yet begun. This ASHRAE Project is being conducted by the National Research Council of Canada and is a broad based fire hazard assessment program developed to evaluate the hazard presented by the accumulation of plenum cables. This question has not yet been answered and developing cable categories to address a hazard that has not yet been defined is premature. The project when completed will assist in developing appropriate language for NFPA 90A and/or the National Electrical Code.

The FPRF project has only issued an interim report dated June 2000. This project has only accomplished a cursory review of one cable type in NFPA 255 and NFPA 259 and has just begun the experimental work on broader aspects of the "limited combustible" definition.

The proposals for the National Electrical Code that have been accepted by Code Making Panel 16 for the removal of all abandoned cable broadly addresses this problem now. The adoption of these proposals for removing all abandoned cable will significantly reduce the fuel load created by excessive cable accumulation.

E. The International Mechanical Code (IMC), the Uniform Mechanical Code (UMC), and the NFPA 90A (the membership and the NFPA Standards Council) have each recently rejected similar provisions to the ones being proposed for the National Electrical Code. These proposals for "limited combustible cables" have been rejected for several reasons including:

a. They will present confusion in the field;

b. They are not good code based on sound engineering principles;

c. They are not based on good fire hazard assessment information; and

d. Questions regarding the appropriateness and accuracy of the test protocols NFPA 255 and NFPA 259.

PANEL ACTION: Reject.

COMMENT ON PROPOSAL NO: 16-232
RECOMMENDATION: Association of Cabling Professionals (ACP) recommends that Code Panel 16 continue to accept this proposal in principle.
SUBSTANTIATION: ACP supports the acceptance and use of limited combustible cable. This cable design provides a significant improvement in fire safety. The NFPRF has demonstrated that cable can be tested and listed for full compliance to the NFPA 255 and 259 protocols. Limited combustible cable is consistent with the full requirements of NFPA 90A and its intended fire safety performance.
PANEL ACTION: Accept.

SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.
COMMENT ON PROPOSAL NO: 16-250
RECOMMENDATION: Continue accepting this proposal in principle, by retaining the phrase: "Abandoned cables, not intended for future use shall not be permitted to remain."
SUBSTANTIATION: There is a potential for increased fire hazard or fire risk when any cable, irrespective of whether it is or is not limited combustible, remains as fuel load unnecessarily once it has been taken out of use. Materials that are limited combustible can also burn (i.e., they are not noncombustible) and also increase the fire load. Furthermore, all abandoned cables can also affect the safety of plenums because of their weight. There is, thus, no justification for permitting any cable to remain in a plenum once it is abandoned and not intended for future use.
PANEL ACTION: Accept in Principle.

16- 308 - (Table 800-53): Reject

Note: "See Technical Correlating Committee action on Comment 16-98."

SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.

COMMENT ON PROPOSAL NO: 16-254

RECOMMENDATION: This proposal should be rejected, the references to CMP-50 and MPP-50 should be deleted from the Table 800-53 and not incorporated into Figure 800-53 and the CMP-50 and MPP-50 classifications should not be created.

SUBSTANTIATION: The CMP-50 and MPP-50 classifications are unnecessary classification because they are not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}
* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}
* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM

E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.

* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."

* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $- C\,H_2 - + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2\,H_3\,Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2\,H_3\,Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\,H_2O + 0.5\,N_2 + 1.25\,O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a\,H_b\,O_c\,F_e + (a+b/4-c/2-e/4)\,O_2 + (n+1/2)*e*(1-x) - b/2)\,H_2O = (a-ex/4)\,CO_2 + ex/4\,CF_4 + e(1-x)\,(HF) + e(1-x)\,n\,H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

ARTICLE 810 — RADIO AND TELEVISION EQUIPMENT

(Log #397)

16- 312 - (810-21(f)(1)d): Reject
SUBMITTER: Dan Leaf, Palmdale, CA
COMMENT ON PROPOSAL NO: 16-266
RECOMMENDATION: Accept in Principle revised:
The nonflexible metallic power service raceway.
SUBSTANTIATION: The Code permits flexible type metallic service raceways. The heading indicates the raceway is used as an electrode. Section 250-70 indicates the grounding conductor shall be connected by welding, pressure connectors, or clamps, none of which appear suitable for connection to flexible raceway. Section 250-118 referred to by the Panel covers types of equipment grounding conductors, which this conductor does not appear to be.
PANEL ACTION: Reject.
PANEL STATEMENT: Section 250-118 permits flexible metal conduit under certain conditions to be used for grounding. Section 250-70(4) allows an equally substantial approved means as a method for attachment to electrodes.

ARTICLE 820 — COMMUNITY ANTENNA TELEVISION AND RADIO DISTRIBUTION SYSTEMS

(Log #1576)

16- 313 - (820-2): Accept in Principle
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-273
RECOMMENDATION: Revise text to read as follows:
Abandoned Cable: Cable that is not ~~neither~~ terminated at both ends, ~~at a connector or other~~ not connected to equipment, or not ~~nor~~ identified for future use with a tag.
SUBSTANTIATION: The term "terminated at a connector" may result in cables being left in place as many cables come with connectors or the installer could add crimp connectors and leave the cables in place. The present language can be easily misunderstood: does the cable have to be terminated and tagged, or is it a choice?
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-314. The revised definition satisfies the submitter's intent.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:
AFFIRMATIVE: 21

(Log #1851)

16- 314 - (820-2): Accept in Principle
SUBMITTER: Robert W. Jensen, dbi-Telecommunications Infrastructure Design
COMMENT ON PROPOSAL NO: 16-273
RECOMMENDATION: New wording:
Abandoned Cable. Installed coaxial cable, with or without coaxial connectors, that is neither terminated at equipment (other than a coaxial connector), nor identified for future use with a tag.
SUBSTANTIATION: BICSI is proposing several clarifications to the definition. First, we add the word installed to show that the cable needs to be installed and not in the installers truck. Second, given the definition of "equipment" in Section 100, a coaxial connector is "equipment", and therefore under the definition initially accepted by the Panel, coaxial cable will always be terminated and therefore never abandoned. Consequently, BICSI is proposing additional wording to clarify the Panel intent, meaning "real" equipment, and not just a connector on the end.
PANEL ACTION: Accept in Principle.
Revise the recommendation to read as follows:
"Abandoned Coaxial Cable. Installed coaxial cable that is not terminated at equipment other than a coaxial connector and not identified for future use with a tag."
PANEL STATEMENT: The revised text more clearly expresses the intended definition and complies with the Manual of Style.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21

(Log #1756)

16- 317 - (820-2-Abandoned Cable): Accept in Principle
SUBMITTER: Francis W. Peri, Communications Design Corporation
COMMENT ON PROPOSAL NO: 16-273
RECOMMENDATION: New wording:
Abandoned Cable. Installed coaxial cable, with or without coaxial connectors, that is neither terminated at equipment (other than a coaxial connector), nor identified for future use with a tag.
SUBSTANTIATION: This definition needs clarification. The word installed shows that the cable needs to be installed and not in the installers truck. Also, considering the definition of "equipment" in Section 100, a coaxial connector is "equipment". Therefore, under the definition initially accepted by the panel, coaxial cable will always be terminated and therefore never abandoned. ACP proposes additional wording to clarify the panel intent, meaning "real" equipment, and not just a connector on the end.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-314. The revised definition satisfies the submitter's intent.

(Log #1582)

16- 319 - (820-3(a)): Accept in Principle in Part
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-313
RECOMMENDATION: Revise text to read as follows:
Spread of Fire or Products of Combustion. Installations in hollow spaces, vertical shafts, and ventilation or air-handling ducts shall be made so that the possible spread of fire or products of combustion will not be substantially increased. Openings around penetrations through fire resistance-rated walls, partitions, floors, or ceilings shall be firestopped using approved methods to maintain the fire resistance rating.
Abandoned cables not intended for future use shall not be permitted to remain.
FPN: Directories of electrical construction materials published by qualified testing laboratories contain many listing installation restrictions necessary to maintain the fire-resistive rating of assemblies where penetrations or openings are made.
SUBSTANTIATION: This definition under the section entitled "Spread of Fire or Products of Combustion" is not consistent throughout the Code. This comment uses language from ROP 16-250 [850-52(B)] to provide a consistent requirement throughout the code.
The same comment is being made for the following sections:
640-3A (ROP 16-1a)
645-5D6 (ROP 12-106)
725-3B (ROP 16-80)
760-3A (ROP 16-144)
770-3A (ROP 16-176)
820-3A (ROP 16-313)
830-3A (ROP 16-364)
820-52B (ROP 16-368)
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: The panel accepts in principle the statement regarding abandoned cables. Refer to panel action on Comment 16-318. This satisfies the submitter's concerns.
The current reference to 300-21 satisfies the balance of the comment, which is rejected. That portion of the comment repeats the text of 300-21.

16- 322 - (820-5): Reject
SUBMITTER: Glenn W. Zieseniss, Crown Point, IN
COMMENT ON PROPOSAL NO: 16-276
RECOMMENDATION: Change the "Accept in Principle" to "Reject".
SUBSTANTIATION: I agree with Mr. Egesdal's and Mr. Speer's negative vote and comment on Proposal 16-192. This proposal is giving a "blanket okay for any type of ceiling tile to support the possible added weight of 3 cables of less than 1/2 in. in diameter on each ceiling tile. The proposal does not affirm that the ceiling tile industry was contacted of adding weight to lay on their product. This product is not part of the building structure, and is not designed to be suitable for supporting cables. I have seen ceiling tiles which look as if made of fiber glass insulation which has a finished surface on the exposed side of the ceiling. It is my belief that this ceiling tile would not accept additional weight upon it. I have contacted three ceiling tile companies or organizations on this proposal. They all suggested that their ceiling tiles are not to support additional weight. I have provided copies of my e-mail contacts.
NOTE: Supporting Material is available at NFPA Headquarters.
PANEL ACTION: Reject.
PANEL STATEMENT: The recommendation of Comment 16-320a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications cables in existing construction. The restrictions contained in Comment 16-320a limit both the number and size of wires and cables permitted on each ceiling panel, thereby controlling weight and accumulation so that cables can be easily moved aside to permit access. The submitter's concern about weight is addressed by decreasing the size of the cable to 1/4 inch and limiting the number of cables to three per each 10 ft x 10 ft area.

(Log #863)

16- 323 - (820-5): Accept in Principle in Part
SUBMITTER: Larry F. Miller, National Electrical Manufacturers Association (NEMA)
COMMENT ON PROPOSAL NO: 16-276
RECOMMENDATION: The Panel should continue to Accept the proposal in Principle but revise the Panel action text to read as follows:
820-5. Access to Electrical Equipment Behind Panels Designed to Allow Access.
Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use <u>or maintenance.</u> Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).
a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.
b.<u>1. Installation of cables in suspended lay-in type ceiling spaces shall comply with 300.11.</u>
<u>2. Installation of cables in other than suspended lay-in type ceiling spaces shall comply with 300.11 where the space is accessible.</u>
<u>3.Where the ceiling is not the lay-in type, and the space is not accessible, three cables less than 13 mm (0.5 in). shall be permitted to be installed unsupported by the building structure between access points or access panels.</u>
~~Buildings with existing cabling systems.~~
~~Where practicable, installation of cables shall comply with Section 300.11. Where impracticable to comply with Section 300.11, cables less than 13 mm (0.5 in) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.~~
~~1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.~~
~~2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum three supported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid."~~
SUBSTANTIATION: We agree with Mr. Egedsal's and Mr. Speer's negative comments that suspended ceilings are not intended to support electrical wires or cables.
Section 300-11(a)(1) (wiring located within the cavity of a fire-rated floor-ceiling or roof-ceiling) allows an exception for wiring that has been tested as part of the fire-rated assembly. This proposal could compromise the fire-rating of the ceiling by overriding that requirement. The words "or maintenance" have been added because so much of the damage occurs in ceiling spaces as various trades perform maintenance.
The submitter states that he has submitted companion proposals for Articles 725 760, 770, 820 and 830. If each of these articles will allow three cables per ceiling tile, this could result in a total of 18 cables per ceiling tile, which appears to be approaching the "excessive accumulation" the submitter agrees could be a hazard. Limiting the size and quantity of cable permitted to be fished in non-lay-in ceiling spaces will help control the weight of cable (combined with that permitted in the other articles referenced above) on these ceilings.
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: The panel rejects the recommended addition of the word "maintenance." The term "normal building use" includes "maintenance." The balance of the recommendation is accepted in principle. Refer to the recommendation and substantiation on Comment 16-320a.

(Log #966)

16- 324 - (820-5): Accept in Part
SUBMITTER: Palmer Hickman, Royersford, PA
COMMENT ON PROPOSAL NO: 16-276
RECOMMENDATION: Reject Proposal 16-276 as amended by Code-Making Panel 16. Accept Proposal 16-276 as submitted by Mr. Brunssen.
SUBSTANTIATION: I request Code-Making Panel 16's reconsideration of their action on this proposal. The proposed 820.5(B)(2) would now permit three cables to be installed on the tiles of a suspended ceiling, without providing any technical substantiation for this allowance.

I understand that this proposed allowance of ceiling support only applies to buildings with existing cabling systems where it is "impracticable" to comply with 300-11. Impracticability does not provide technical substantiation to allow a ceiling assembly that has not been evaluated to support the potential additional load of three cables on each and every ceiling tile.

I am aware that Chapter 8 is independent of other chapters except where specifically referenced therein. Panel 16 has referenced 300-11, and Code-Making Panel 3 is on record reaffirming their prohibition of ceiling assemblies being used beyond the manufacturers design parameters in the Panel Statement to Comments 3-53 and 3-57 of the 1998 ROC, and Proposal 3-68 of the 2001 ROP. In the latter reference, Code-Making Panel 3 states: "The panel reaffirms its position that an independent means of support shall be provided for all wiring, not just branch circuit wiring...".

The substantiation provided by Mr. Brunssen for his proposal does not support the proposed change as amended by Code-Making Panel 16. He claims that "a limited amount of cabling laid directly on a suspended ceiling is permitted..." without stating where this permission is given. The entire substantiation of the submitter seems contrary to the action of the panel. I am not sure he would recognize the end result as the proposal he made. Mr. Brunssen begins his substantiation by stating that "Section 820-5 may be misinterpreted to mean that conductors and cables may not be placed directly on the suspended ceiling." He notes that the 1999 Handbook "Figures, 820-1 and 820-2 lead the reader to conclude that no conductors or cables are permitted to rest directly on the suspended ceilings." The submitter also stated Code-Making Panel 16 responded to a proposal to Article 725 (1992 TCD Comment 16-18) that the proposed requirement "...would still allow some cabling of a limited quantity above the ceiling tile, but not to an excessive amount." Note the words "above the ceiling tile", not on the ceiling tile. I feel these examples are not misinterpretations, but rather correct interpretations, and a case to reject this proposal as amended by Code-Making Panel 16.

In conclusion, I respectfully disagree with the Panel Action on this Proposal. I find no technical substantiation to warrant such a dramatic change. Mr. Brunssen presented a well-researched proposal addressing access, not support. The substantiation of the submitter does not support this change, nor does the Panel Statement.
PANEL ACTION: Accept in Part.
PANEL STATEMENT: The panel accepts the portion of the comment to retain Section 820.5, and rejects the portion of the comment to reject Proposal 16-176. Refer to the recommendation and substantiation on Comment 16-320a. Also refer to the panel action and statement on Comment 16-322.

(Log #1153)

16- 325 - (820-5): Accept in Principle
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-276
RECOMMENDATION: Continue to accept in principle.
SUBSTANTIATION: Panel 16 should continue to accept in principle as it provides a reasonable and safe solution to placing a limited number of signaling and communications wires and cables in existing construction. The restrictions contained in the proposed change limit both the number and size of wires and cables permitted on each suspended ceiling panel. In this manner additional weight, as well as an accumulation of wires and cables that would otherwise restrict access above suspended ceiling panels, is controlled and limited. The limited number of cables permitted can easily be moved aside to permit access. Some concern has also been expressed that cables placed directly on the ceiling panels would degrade the fire rating of the ceiling. The suspended ceiling, part of a membrane that is intended to retard fire from spreading into the ceiling cavity, would be unaffected in its ability to retard the spread of fire by a limited number of wires and cables resting on top of the panels. This is a companion comment and is intended to correlate with comments on Proposals 16-38, 16-112, 16-159, 16-192, and 16-332.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to the substantiation on Comment 16-320a. This action meets the intent of the submitter.

(Log #1161)

16- 326 - (820-5): Accept in Principle
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-276
RECOMMENDATION: Revise as follows:

820-5. Access to Electrical Equipment Behind Panels Designed to Allow Access. Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).

a. New Building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.

b. Buildings within existing cabling systems. Where practicable, installation of cables shall comply with Section 300-11. Where impracticable to comply with Section 300-11, cables less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.

1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.

2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum <u>of</u> three unsupported cables on top of ~~any one~~ <u>each</u> ceiling tile, <u>i.e, up to three wires and cables are permitted to lay on a ceiling tile.</u> The cables shall be run parallel to the ceiling grid.

SUBSTANTIATION: Proposed Section 820-5(b)(2), as presently written in Proposal 16-276, panel action, is confusing and could be interpreted as permitting a total of only three unsupported wires and cables above a suspended ceiling. The intent of the panel was that up to a maximum of three unsupported wires and cables may be routed across each and every ceiling tile. The revision proposed in this comment clarifies and accomplishes the intent of the panel. This is a companion comment and is intended to correlate with comments on Proposals 16-38, 16-112, 16-159, 16-192, and 16-332.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to the recommendation and substantiation on Comment 16-320a.

Note: The Technical Correlating Committee directs that the references to Articles 640 and 650 be deleted because the panel did not accept similar requirements in those articles. The Technical Correlating Committee also directs that the FPN which contains a mandatory requirement be deleted to comply with the NEC Style Manual.

SUBMITTER: CMP 16

COMMENT ON PROPOSAL NO: 16-276

RECOMMENDATION: Retain the existing 1999 code text for Section 820-5 (unmodified).

Add new Section 820.7 to read as follows:

820.7 Installation of Systems.

CATV systems shall be installed in compliance with A or B.

A. New Ceiling Construction. The installation of cables in new ceiling construction shall comply with Section 300-11.

B. Existing Ceilings.

1. Fire-Rated Ceilings. The installation of cables in the cavity of an existing fire-rated ceiling assembly shall comply with Section 300-11.

2. Non-Fire-Rated Ceilings. For installations in the cavity of an existing non-fire-rated ceiling assembly, cables less than 6 mm (0.25 in) in diameter shall be permitted to be installed unsupported from the building structure in accordance with the following:

a. Fixed or Hard Ceilings. In areas having fixed or hard ceilings with access points or access panels, a combined total of three cables from Articles 640, 650, 725, 760, 770, 800, 820 and 830, shall be permitted to be placed between access points or access panels in the ceiling. Additional cables shall be installed in accordance with 300.11.

b. Suspended Lay-In Ceilings. In areas having suspended lay-in ceilings, in any 3 m by 3m (10 ft. x 10 ft) ceiling area, a combined total of three cables from Articles 640, 650, 725, 760, 770, 800, 820 and 830, shall be permitted to be installed directly on the ceiling grid. Additional cables shall be installed in accordance with 300.11.

FPN. Cables of all types are included in the total limit of three cables, not three cables from each article.

SUBSTANTIATION: Proposal 16-276 was accepted in principle to permit the installation of unsupported cables under limited conditions. Proposal 16-276 text, however, was too broad and unclear. The text of this comment clarifies the original intent. The new text includes requirements to comply with Section 300.11. Permitted installation conditions will not compromise the integrity of fire-rated ceilings. For non-fire-rated ceilings, the permitted relief from Section 300.11 is limited to very specific conditions. Section 820.5 is not being modified because the accessibility requirements should remain.

PANEL ACTION: Accept.

16- 330 - (820-5(b)): Accept in Principle in Part

SUBMITTER: Richard P. Owen, City of St. Paul, Electrical Inspection

COMMENT ON PROPOSAL NO: 16-276

RECOMMENDATION: Replace (b) of the proposal with the following text:

(b) Buildings not Covered Under (a) Above. In areas having ceilings with access points or panels and having 900 mm (3 ft) or less vertical clearance above the ceiling, it shall be permissible to fish a maximum of 3 cables, each less than 13 mm (0.5 in.) in diameter, between access points in the ceiling.

SUBSTANTIATION: The Technical Correlating Committee directed Panel 3 Chair Raymond Weber to form a Task Group to review these proposals and to submit the results as comments to Panel 16. Task Group 3-16, consisting of Chair Weber, members Steven Speer; Lee Hewitt; Richard Owen and Ron Maassen held a conference call on October 3, 2000 and developed the above language as a comment. The Task Group was concerned with allowing unsupported cabling above suspended ceilings, since companion proposals for Articles 725, 760, 770, 800, 820 and 830 would also allow this limited cabling without support. The possible accumulation of cable allowed by all these articles would be excessive and would both limit access to a ceiling and conflict with Section 300.11. Rewording of (b) also eliminated the unenforceable terms "practicable" and "impracticable" as directed by the Technical Correlating Committee.

PANEL ACTION: Accept in Principle in Part.

PANEL STATEMENT: The panel rejects the specific limitations in the comment but accepts the principle of permitting a limited number of cables. The recommendation of Comment 16-320a provides a reasonable, safe, and practical solution to placing a limited number of unsupported CATV cables in existing construction.

(Log #1258)

16- 331 - (820-5(b)(2)): Reject
SUBMITTER: J. Paul Spinn, USG Research & Technology Center
COMMENT ON PROPOSAL NO: 16-276
RECOMMENDATION: Delete the following text:
In areas having suspended lay in ceiling, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.
SUBSTANTIATION: By allowing a maximum of three unsupported cables on top of any one (or more) ceiling tiles, the fire-rating of the assembly and the Class A surface burning characteristic requirement, which includes flame spread and smoke development, could be jeopardized. By decreasing the fire-rating of the plenum assembly and the surface burning characteristic of the ceiling tile, the life safety of the occupants can be negatively affected. By rejecting this proposal, these problems can be eliminated.
To substantiate the comment made for the proposal, four key points are provided:
[1] For a fire rated floor/ceiling or roof/ceiling assembly, placement of unsupported cables on top of any one ceiling tile or a row of ceiling tiles could invalidate the fire-rating for a particular assembly. The rationale for this argument are:
(a) The weight of the cables could cause premature tile fallout leading to an early failure of the assembly, which is tested in accordance with NFPA 251 or ASTM E 119.
(b) The increased heat of combustion associated with the cable jackets, which commonly use plastics, will add to the total fire load of an assembly. As the total fire load increases for an assembly, the fire endurance of the assembly will decrease, which could jeopardize an assembly's fire-rating.
[2] For a Class A ceiling, placement of unsupported cables on the ceiling can effect flame spread and smoke development performance and jeopardize the required Class A rating for the ceiling tiles. The rationale for this argument are:
(a) The flame spread will increase due to the increased total heat load, which is caused by the plastic on the cable jacket.
(b) The smoke development will increase due to the cable jackets, which are usually plastic such as PVC or CPVC.
[3] The placement of unsupported cables on top of any one or more ceiling tiles presents potential life safety issues for occupants due to the decreased fire-rating of the floor/ceiling or roof/ceiling or an increase in the ceiling surface burning characteristics.
[4] Placement of unsupported cables on top of any one ceiling tile or a row of ceiling tiles would increase ceiling tile sag due to increased weight of the cables on the ceiling tiles, and would impair the accessibility of the ceiling plenum.
PANEL ACTION: Reject.
PANEL STATEMENT: The recommendation of Comment 16-320a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications cables in existing construction. The restrictions contained in Comment 16-320a limit both the number and size of cables permitted on each ceiling panel, thereby controlling weight and accumulation so that cables can be easily moved aside to permit access. The submitter's concern about weight is addressed by decreasing the size of the cable to 1/4 inch and limiting the number of cables to three per each 10 ft x 10 ft area. The revised text precludes the installation of cables in all fire-rated ceiling assemblies.

(Log #2087)

16- 332 - (820-5(b)(2) (New)): Accept in Principle in Part
SUBMITTER: Marcelo M. Hirschler, GBH International
COMMENT ON PROPOSAL NO: 16-276
RECOMMENDATION: Revise text as follows:
820-5. Access to Electrical Equipment Behind Panels Designed to Allow Access
Access to equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).
a. New building construction (e.g. renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.
b. Buildings with existing cable systems. Where practicable, installation of cables shall comply with Section 300.11. Where impracticable to comply with Section 300.11, in those areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables less than 13 mm (0.5 in) in diameter, between access points in the ceiling. ~~cables less than 13 mm (0.5 in) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.~~
~~1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.~~
~~2. In areas having suspended lay in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.~~
SUBSTANTIATION: The permission granted by the panel to install cables on suspended ceiling tiles should be rescinded. Neither cables nor any other item should be installed on top of a suspended ceiling tile. The support systems of suspended ceilings are not designed to resist any significant amount of weight without being deflected or broken.
This issue has been raised on Proposal 16-192 (log 1665) in negative comments by two panel members, Mr Egesdal and Mr Speer, who both correctly point out that suspended ceiling tiles are not intended to support the weight of electrical cables. Mr. Sandy Egesdal repeats his negative comment on this proposal.
The point made by the Technical Correlating Committee on proposal 16-38 that such use would constitute an exposed use of cables is an additional consideration to rejecting this part of the proposal.
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: The panel accepts the principle of permitting a limited number of cables to be installed in a fixed or hard ceiling. The panel rejects the balance of the submitter's recommendation including the limiting of the installation of cables in a suspended lay-in ceiling . The recommendation of Comment 16-320a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications cables in existing construction.

(Log #1159)

16- 333 - (820-6): Reject
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-276a
RECOMMENDATION: Delete 820-6 and incorporate the information in 820-5 as follows:
820-5. ~~Access to Electrical Equipment Behind Panels Designed to Allow Access.~~ Mechanical Execution of Work. Community antenna television and radio distribution systems shall be installed in a neat and workmanlike manner. Access to electrical equipment shall not be denied by an accumulation of ~~wires and~~ cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. ~~Access to electrical equipment behind ceilings designed to allow access~~ Cables installed exposed shall comply with (a) or (b).
a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11 Cables shall be supported by structural components of the building. Such cables shall be attached to structural components at intervals not exceeding 1.52 m (5 ft) and within 305 mm (12 in.) from every cabinet, box or fitting by straps, staples, hangers or

similar fittings designed and installed so as not to damage the cable. The installation shall also conform with Section 300-4(d).

b. Buildings with existing cabling systems. Where practicable, installation of cables shall comply with ~~Section 300-11~~ 820-5(a) Where impracticable to comply with ~~Section 300-11~~ 820-5(a), cables less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.

1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.

2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.

SUBSTANTIATION: This is a companion comment and is intended to correlate with similar comments on Proposals 16-39, 16-115, 16-159a, 16-192a, and 16-333a. Sections 820-5 and 820-6 actually address the same issue, the mechanical execution of work. Accessibility behind panels designed to allow access is really an "execution of work" issue. Additionally, the Technical Correlating Committee has identified a potential conflict between the panel action on Proposals 16-38 and 16-39, that would also result here in 820. This comment editorially combines 820-5 and 820-6 into a single Section 820-5 requiring attachment to the building structure of exposed cables and conductors and, where impracticable to do so, permits a limited number of cables of specified maximum size to be placed on suspended ceiling tiles. It accommodates the intent of both proposals that cables should be supported by the building structure, but in extenuating circumstances in existing construction, a limited number and weight of cables may be placed on a suspended ceiling. Further, in the first paragraph of 820-5, the phrase "wires and" is deleted as CATV circuits are provided via coaxial cable and not wire.

PANEL ACTION: Reject.

PANEL STATEMENT: The sections should not be combined. Refer to the recommendation and substantiation for Comment 16-320a where these recommendations are addressed.

SUBMITTER: Steven C. Johnson, Time Warner Cable

COMMENT ON PROPOSAL NO: 16-281

RECOMMENDATION: Reject the proposal to prohibit use of service masts for drop attachments.

SUBSTANTIATION: There is no reason to force a homeowner to install a separate mast to accommodate communications (telephone, CATV) service drops wherever the service mast can be listed to do so. An arbitrary prohibition of attaching to electrical masts is not reasonable. Where the mast can be shown to support additional attachments without creating a safety hazard, these attachments should be allowed. Reasonable qualifications would include the ability to support the weight (with ice loading) and not damage the mast or structure, ability to maintain proper clearance, etc.

PANEL ACTION: Accept in Principle.

PANEL STATEMENT: Refer to the panel action and statement on Comment 16-337.

NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21

VOTE ON PANEL ACTION:

AFFIRMATIVE: 16

NEGATIVE: 5

EXPLANATION OF NEGATIVE:

DORNA: See my explanation of negative vote on Comment 16-271.

KAHN: The comments should be rejected and the original Panel Action to Reject Proposal 16-281 should be sustained.

Code-Making Panel 4 has rejected the Proposal and that panel has primary jurisdiction. In their Panel Statement, they state: "... that they do not believe that the listing of the product will adequately address the personnel issues that are created by the co-mingling of the different systems on a common mast. Issues such as loading can be addressed by the proposed listing, however personnel safety cannot be assured regardless of the listing criteria." I agree with their assessment.

A task group of Code-Making Panel 4 and Code-Making Panel 16 members as suggested in the Panel Statement should be formed to study the problem further if the Technical Correlating deems it advisable.

MANGAN: See my explanation of negative vote on Comment 16-271.

SPEER: See my explanation of negative vote on Comment 16-271.

TODD: See my explanation of negative vote on Comment 16-155.

(Log #1145)

16- 337 - (820-10(c)):

Note: The Technical Correlating Committee directs that this comment be reported as "Reject" to correlate with the action on Proposal 4-73 and Comment 4-51

SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.

COMMENT ON PROPOSAL NO: 16-281

RECOMMENDATION: Accept the proposal.

SUBSTANTIATION: This is a companion comment to my comment on Proposal 4-73 wherein it was proposed to revise Section 230-28 to permit communications wires and cables to be attached to a service mast that is listed for the purpose. Code-Making Panel 4 has been asked to reconsider their rejection of Proposal 4-73, based on the panel statement that Code-Making

Panel 4 does not "believe" listing will adequately address the personnel safety issues. Code-Making Panel 4's position is contrary to both the industry and NEC accepted method to ensure the safety of wiring, cable, and equipment when used for its intended application, that of listing by a Nationally Recognized Testing Laboratory (NRTL). Listing will ensure that the service mast can adequately support multiple attachments while providing for the safety of power, communications, and CATV technicians who must access the service mast. Code-Making Panel 16 stated that detailed design and installation requirements are not defined. This is the purpose of listing - to establish that a product will be safe when used as intended. It is unreasonable to arbitrarily prohibit attaching to the electric service mast and cause the homeowner to bear the cost of a separate mast for communications. When the mast is listed and installed properly for its intended use, it will be capable of safely supporting, and safely permitting access to, multiple attachments. Code-Making Panel 16 should accept Proposal 16-281 based on the merits of the submitter's original substantiation, contingent upon the action of Code-Making Panel 4.

Note also companion comments to Proposals 16-202 and 16-344.

PANEL ACTION: Accept.

PANEL STATEMENT: CMP 16 understands that CMP 4 has primary jurisdiction over requirements associated with the power service mast. A companion comment has been submitted to CMP 4 to allow relief for the attachment of communications cables to the power service mast. Should CMP 4 continue to reject the proposal, CMP 16 requests that the Technical Correlating Committee assign a task group consisting of members of both panels to review the issues.

16- 339 - (820-12): Accept

SUBMITTER: Andy Scott, National Cable Television Association

COMMENT ON PROPOSAL NO: 16-285

RECOMMENDATION: Reject Proposal 16-285.

SUBSTANTIATION: NCTA, on behalf of the cable television industry, strongly supports Panel 16's action to reject this proposal. The proposal contains references to telephony indicating that the requirement should more correctly apply to Articles 800 or 830. However, both 800 and 830 already require protection be installed. Additionally, the proposal references communications wires and cables without metallic shielding. However, in the case of cable television, 820's scope indicates the use of coaxial cables, which inherently include metallic shielding. Furthermore, data collected from cable television set top manufacturers indicate a negligible (less than 0.02 percent) problem with failures due to surges coming in on the coaxial input. To our knowledge, no incidents of harm or damage to consumer owned electronics from the coaxial input that were the result of existing practices have been documented to support this proposal.

PANEL ACTION: Accept.

COMMENT ON PROPOSAL NO: 16-288

RECOMMENDATION: Accept Proposal 16-288.

SUBSTANTIATION: NCTA, on behalf of the cable television industry, strongly urges Panel 16 to accept this proposal. The point of attachment does not necessarily coincide with the point of entrance. Cable industry practice is to attach to the building near its electrical ground and bond at that point. The location of the customer premises equipment necessitates that the cable enters the building near that location. Where this point does not coincide with the location of the building electrical ground, the present code wording requires a technically inferior grounding condition.

PANEL ACTION: Accept in Principle.

PANEL STATEMENT: The panel action text of Proposal 16-288 satisfies the submitter's intent and includes the panel action on Proposal 16-286.

(Log #1119)

16- 342 - (820-40(a)(4)): Reject

SUBMITTER: Steven C. Johnson, Time Warner Cable

COMMENT ON PROPOSAL NO: 16-293

RECOMMENDATION: Reject Proposal 16-293.

SUBSTANTIATION: 1. The distance between entrances for different services is practically limited to 100 feet for most installations which corresponds to 0.3 ohms for 14 AWG solid copper conductor and 0.05 ohms for 6 AWG solid copper conductor. Neither resistance is significant. The new 820-40(a)(4) proposed would mandate placing an additional electrode wherever the distance between the grounding terminal for communications cables and the electrical service ground is greater than 20 feet. The

additional electrode would not significantly decrease resistance to ground nor increase safety.

2. The practical difference between the existing code and the proposed change is that the grounding conductor size is increased to 6 AWG every time the 20 foot distance rule is violated. This difference results in 0.25 ohm difference in the extreme case of 100 feet grounding conductor run. The difference is usually significantly less than 0.25 ohms since the distance is usually less than 100 feet and the size of the grounding conductor is normally larger than 14 AWG. The requirement for approximately equal ampacity for cable sheath and grounding conductor in 820-40(3) results in larger grounding conductor than 14 AWG in most cases.

3. The proposal provided no technical justification for the quantified 20-foot limitation and no demonstrated improvement in safety. No problems are cited and no incidents of damage or harm are presented that are the result of present installation and bonding practices.

4. The 20 foot rule is not always practical to maintain. The new proposal would result in a backlash from homeowners whenever an additional electrode is to be placed and 6 AWG wire to be used to bond it to the existing electrode system.

PANEL ACTION: Reject.

PANEL STATEMENT: The panel's intent is to limit the potential difference between power and communications circuits during lightning events.

That potential difference is generally a function of conductor inductance (L), which increases in direct proportion to conductor length, and the rate of rise of the current (di/dt). This proposal addresses that issue, encourages short coaxial cable, shield grounding conductors, provides guidance as to a reasonable maximum length, and provide an alternative where it is not practicable to meet the maximum length (20 ft) restriction. The proposed length restriction is limited to one- and two-family residences as it is such installations that are more likely to have diverse power and communications entrances and experience lightning-related
problems (urban/suburban environment with a fewer elevated structures and extensive buried metallic objects).

(Log #1648)

16- 343 - (820-40(a)(4)): Reject

SUBMITTER: Andy Scott, National Cable Television Association

COMMENT ON PROPOSAL NO: 16-293

RECOMMENDATION: Reject Proposal 16-293.

SUBSTANTIATION: The Cable Television industry urges the NFPA to reject this proposal. These proposals have no technical merit and no demonstrated improvement in safety. To our knowledge, no incidents of harm or damage that were the result of existing installation and bonding practices have been documented to support such a change in existing practice.

The practice within the cable industry is to maintain grounding conductors as short as practicable. In the majority of installations, the distance between entrances for different services is limited to approximately 100 ft. This distance corresponds to 0.3 ohms for 14 AWG solid copper conductor and 0.05 ohms for 6 AWG solid copper conductor. Neither resistance is significant. Notwithstanding the additional increase in installation cost to the customer, the 20 ft rule cannot be practically maintained, and would result in a negative reaction from homeowners whenever an additional electrode is to be placed and 6 AWG wire to be used to bond it to the existing electrode system.

PANEL ACTION: Reject.

16- 353 - (820-51(b) (New)): Reject
Note: "See Technical Correlating Committee action on Comment 16-98."
SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.
COMMENT ON PROPOSAL NO: 16-302
RECOMMENDATION: This proposal should be rejected, the new section 820-51(b) should not be created and the CATVP-50 classification should not be created.
SUBSTANTIATION: The CATVP-50 classification is an unnecessary classification because it is not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of

plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}
* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}
* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in. (51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.
* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."
* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials

of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $- C\,H_2 - + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2\,H_3\,Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2\,H_3\,Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\,H_2O + 0.5\,N_2 + 1.25\,O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a\,H_b\,O_c\,F_e + (a+b/4-c/2-e/4)\,O_2 + (n+1/2)*e*(1-x) - b/2)\,H_2O = (a-ex/4)\,CO_2 + + ex/4\,CF_4 + e(1-x)\,(HF) + e(1-x)\,n\,H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

Note: "See Technical Correlating Committee action on Comment 16-98."
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-302
RECOMMENDATION: Delete proposed section 820-51(b) and associated notes.
SUBSTANTIATION: The introduction of a new class of cable ("Limited Combustible Cable") is premature at this time for the following reasons:
A. The note to the definition section 725.71(B), FPN No. 1 references NFPA 90A, Standard for the Installation of Air-Conditioning and Ventilating Systems for the definition of limited combustible. That definition is as follows:
"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141J/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):
a. Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50;
b. Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be combustible."
This definition was established and is applied to building construction materials and not to specific wiring methods or technologies for use in buildings. NFPA 255 and NFPA 259 were never intended for the evaluation of multi-component systems such as electrical and optical cable. More current test methods (other than NFPA 255 and 259), such as NFPA 262, the cone calorimeter, etc. provide reproducible smoke obscuration, flame spread, or heat release (not heat value) information and are more appropriate for measuring the fire hazards of cable. Not all parts of this "Limited Combustible" definition have been applied to the broad scope of cables. Until this definition can be shown as appropriate for cables (attainable and reproducible) it should not be deemed credible and supported by the National Electrical Code at this time. Referencing this inappropriate definition in the National Electrical Code is misleading and bad code.
B. The note references NFPA 255 as the test standard for smoke developed index. This test is not an appropriate test for cables for the following reasons:
a. NFPA 255 has not been harmonized, as has NFPA 262. NFPA 262 has a proven record, unlike NFPA 255.
b. NFPA 255 is not reproducible, whereas NFPA 262 has been shown to be reproducible. This lack of reproducibility has been demonstrated numerous times in round-robin testing of building materials among multiple labs.
The most recent example of this reproducibility problem has been demonstrated in the Interim Report of the Fire Protection Research Foundation (FPRF) "Limited Combustible Cable" (ex. "Permanent Plenum Cable") project, dated June 2000. This report states "The flame spread and smoke measurements in NFPA 255 show good repeatability but relatively poor reproducibility, i.e., the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error." (Page 9, section 4.1.2). In this case, with only two laboratories participating, errors in reproducibility were in the range of 100 percent. Given that numerous fire-testing tunnels exist, the range of error can be expected to be even larger.
This test is inappropriate for cables as the cables are installed against the top of the tunnel. This orientation is not similar to normal cable installations, and cable placement on top of the wire mesh is random in the tunnel.
C. Cable installed above ceilings does not become involved in the fire until near or at flashover. At that point in the fire development, the ceiling tile is falling to expose the cable. Cables in walls or below floors are generally exposed to the fire conditions even later in the fire development. These cables do not spread flame more than 5 ft when tested in accordance with NFPA 262. The proposed restrictions on cable appear excessive based on the fire record.
D. There is not a need established (fire record or hazard analysis) for a new cable category. There are two research projects that are intended to provide information on the fire hazard of cables. The ASHRAE project has not yet begun. This ASHRAE Project is being conducted by the National Research Council of Canada and is a broad based fire hazard assessment program developed to evaluate the hazard presented by the accumulation of plenum cables. This question has not yet been answered and developing cable categories to address a hazard that has not yet been defined is premature. The project when completed will assist in developing appropriate language for NFPA 90A and/or the National Electrical Code.
The FPRF project has only issued an interim report dated June 2000. This project has only accomplished a cursory review of one cable type in NFPA 255 and NFPA 259 and has just begun the experimental work on broader aspects of the "limited combustible" definition.
The proposals for the National Electrical Code that have been accepted by Code Making Panel 16 for the removal of all abandoned cable broadly addresses this problem now. The adoption of these proposals for removing all abandoned cable will significantly reduce the fuel load created by excessive cable accumulation.
E. The International Mechanical Code (IMC), the Uniform Mechanical Code (UMC), and the NFPA 90A (the membership and the NFPA Standards Council) have each recently rejected similar provisions to the ones being proposed for the National Electrical Code. These proposals for "limited combustible cables" have been rejected for several reasons including:
a. They will present confusion in the field;
b. They are not good code based on sound engineering principles;
c. They are not based on good fire hazard assessment information; and
d. Questions regarding the appropriateness and accuracy of the test protocols NFPA 255 and NFPA 259.
PANEL ACTION: Reject.

16- 361 - (820-52(b)): Accept in Principle in Part
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 6-311
RECOMMENDATION: Revise text to read as follows:
Spread of Fire or Products of Combustion. Installations in hollow spaces, vertical shafts, and ventilation or air-handling ducts shall be made so that the possible spread of fire or products of combustion will not be substantially increased. Openings around penetrations through fire resistance-rated walls, partitions, floors, or ceilings shall be firestopped using approved methods to maintain the fire resistance rating.
Abandoned cables not intended for future use shall not be permitted to remain.
FPN: Directories of electrical construction materials published by qualified testing laboratories contain many listing installation restrictions necessary to maintain the fire-resistive rating of assemblies where penetrations or openings are made.
SUBSTANTIATION: This definition under the section entitled "Spread of Fire or Products of Combustion" is not consistent throughout the Code. This comment uses language from ROP 16-250 [850-52(B)] to provide a consistent requirement throughout the code.
The same comment is being made for the following sections:
640-3A (ROP 16-1a)
645-5D6 (ROP 12-106)
725-3B (ROP 16-80)
760-3A (ROP 16-144)
770-3A (ROP 16-176)
820-3A (ROP 16-313)
820-3A (ROP 16-364)
830-58B (ROP 16-368)

EXPLANATION OF ABSTENTION:
CAUDILL: The Society of the Plastics Industries could not reach a consensus position on this issue.

(Log #1069)

16- 363 - (820-53): Reject
Note: "See Technical Correlating Committee action on Comment 16-98."
SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardent Chemicals Assoc.
COMMENT ON PROPOSAL NO: 16-316
RECOMMENDATION: This proposal should be rejected, the references to CATVP-50 should be deleted from the Table 820-53 and not incorporated into Figure 820-53 and the CATVP-50 classification should not be created.
SUBSTANTIATION: The CATVP-50 classification is an unnecessary classification because it is not justified either by requirements for reduction in fire hazard in plenums (fire hazard is the potential for harm associated with fire) or a general reduction in fire risk (fire risk is the combination of fire hazard and the probability of fires resulting in undesirable outcomes). Furthermore, they are based on a research project which is incomplete (according to the Interim Report issued) and they are based on flawed testing technology, as represented by the oxygen bomb calorimeter.

The Plenum Cable Association endorses use of fire hazard assessment and fire risk assessment in order to further develop technically supportable standards, codes and regulations, that ensure reasonable and justifiable classification and control of plastic and other combustible products. The creation of the (CXP-50) marking is not justified based on fire hazard or on fire risk and is simply an effort for one type of material to gain market share at the expense of others. If a search for better fire performance is continued indefinitely, without taking into account the overall fire safety required by the application, clearly the use of plastics and other combustible materials should be discontinued, as a non combustible material can always be found which outperforms any plastic material. Thus, if the National Electrical Code were to support unjustified improvements in fire performance, eventually any use of plastic or other combustible materials would be in jeopardy.

Thus, there are 4 reasons to oppose the CXP-50 classifications: (i) no justification based on fire risk, (ii) no justification based on fire hazard, (iii) the study for the development of the classification by the proponents is incomplete, and (iv) the technique of oxygen bomb calorimetry, and the concept of limited combustible, are technically flawed. These concerns are exemplified as follows:

(i) An analysis of fire performance of cables addresses fire hazard.

Fire hazard analysis: Traditional CMP-rated cables will not cause significant flame spread or smoke obscuration unless the fire source is very large. For example, a CMP cable with a PVC jacket and FEP insulation was shown to have no significant flame spread (out of a possible flame spread of 20 feet) and a peak optical density of much less than 0.2 when exposed to a fire of approximately 1 MW, from a wood crib, in a full scale facility, that simulated a room and plenum [Reference: L.M. Caudill, J.R. Hoover, J.T. Walnock and J.T. Chapin, "Fire Performance of Communications Cables in Concealed Spaces", pages 277-285, NFPRF Fire Risk and Hazard Assessment Symposium, June 26-28, 1996, San Francisco, CA]. The same cable also showed approximately 2 feet flame spread in the NFPA 262 plenum cable test, with a peak optical density not exceeding 0.3, according to the same reference. Clearly, if a cable does not spread flame significantly when a 1 MW fire source is applied, it does not represent any severe fire hazard. In a different scenario, a similar type of cable was studied by the European research project FIPEC, and found to release 42 kW and less than 6 MJ, to spread flame vertically for only 1.1 m, and to give low smoke release when tested in a severe vertical cable tray test (30 kW input at high air flow rate) [Reference: Fire Performance of Electric Cables Report, Interscience Communications, UK, 1999]. This indicates that the fire hazard associated with traditional CMP cables (and this with traditional CL2P and CL3P cables) is very low.

(ii) Analysis of NFPA statistics serves to illustrate fire risk. NFPA statistics address the following types of fires:

* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/roof assemblies" {Roof plenums are examples of these spaces}
* "Non residential concealed space structure fires involving ignition of fixed wiring in ceiling/floor assemblies" {Floor plenums are examples of these spaces}

In each case, the statistics can distinguish whether wire and cable insulation was or was not the item first ignited, giving four sets of statistics relevant to plenum cables. These statistics are relevant to the fire risk from plenum cables, as plenum cables are the typical type of wire and cable insulation present in roof plenums or in floor plenums.

Fire risk analysis: The statistics indicate that, between 1980 and 1996, there have been an average of only 584 fires per year, and of those only 171 have started with ignition of a wire and cable product, and the trend has been downwards (see the attached Tables with fire statistics and the attached charts, indicating a similar type of downward trend for both concealed roof spaces and concealed floor spaces). In fact, over the entire period between 1980 and 1996 the total number of fires in concealed roof spaces involving ignition of fixed wiring has been 0.29% of the total number of non residential structure fires (of which less than 30% started in wire and cable) and the total number of fires in concealed floor spaces involving ignition of fixed wiring has been 0.10% of the total number of non residential structure fires (of which ca. 32% started in wire and cable). With regard to fatalities or injuries: out of 3,734 fatalities in non residential structure fires, only 7 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.19%), and out of 60,950 injuries in non residential structure fires, only 85 occurred in concealed roof or floor spaces involving ignition of fixed wiring (less than 0.14%). At least 4 of the 7 fatalities have been shown not to have resulted from plenum cable fires with the other 3 unknown. Thus, the fire record in a period when the amount of installed plenum cables increased from virtually none to some 20 billion feet, indicates that the fire risk is minimal.

(iii) The classifications of CXP-50 are not yet ready for application, since the NFPA Fire Protection Research Foundation Project developing the classification has not yet issued its final report. The Interim Report (International Limited Combustible Plenum Cable Fire Test Project, Interim Report, by F.B. Clarke and R.G. Gewain, June 2000) is the source of our [Plenum Cable Association] concerns. The first objective of this project was to: "Develop harmonized Steiner Tunnel listing protocols for permanent plenum cables related to NFPA 262/UL 910 and NFPA 255." The Interim Report describes part of Phase I of the project, wherein no harmonized listing protocol has been developed. The Interim Report addresses NFPA 255 and NFPA 259 and states, among other things:

* NFPA 255, flame travel distance: "... The NFPA 255 flame travel distances appear to be highly repeatable {i.e. within one lab} in each laboratory, as evidenced by the small variance of the measurements, *but not particularly reproducible* {i.e. between labs}, as can be seen by comparing this variance with the interlaboratory results. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255, smoke index, or SDI: "... With respect to the smoke measurements, multiple determinations of the SDI by a given laboratory on a given cable agree with one another quite closely *but the SDI's reported by the two labs for the same cables do not appear to be close at all*. The results reported by Laboratory 2 are, with one exception, systematically higher than those of Laboratory 1. ..." {Emphasis added, but statement comes verbatim from report}
* NFPA 255 precision: " ... The flame spread and smoke measurements in NFPA 255 show ... *relatively poor reproducibility*, i.e. the result for a cable in a given laboratory can be repeated with precision but the difference in results between laboratories is on average considerably larger than the repeatability error. ..." {Emphasis added, but statement comes verbatim from report}
* Procedure for NFPA 255: "It is possible to test wire and cable following the current NFPA 255 test procedure, using the mounting specified for plastics in Appendix B7 of the standard." Appendix B-7 of NFPA 255 states:

"B-7 Plastics. B-7.1 The term plastics includes foams, reinforced panels, laminates, grids, and transparent or translucent sheets.

B-7.2 Where any plastic remains in position in the tunnel during a fire test, no additional support is necessary. Thermoplastic materials and other plastics that do not remain in place should be supported by 1/4-in. (6.3-mm) round metal rods or 3/16 in. (4.8 mm) thick 2 in. (51 mm) wide steel bars, or 2-in.

(51-mm) galvanized hexagonal wire mesh supported with metal bars or rods spanning the width of the tunnel."

It is interesting to compare this with the statements in NFPA 262, as follows:

"1-1.3* Although this test uses equipment similar to that used in NFPA 255, Standard Method of Test of Surface Burning Characteristics of Building Materials, and ASTM E 84, Standard Test Method for Surface Burning Characteristics of Building Materials, sufficient changes have been made to the chamber so that a test conducted in the apparatus used for NFPA 255 or ASTM E 84 cannot be considered identical or produce comparable results.

A-1-1.3 The changes made in equipment for this test were deemed necessary in order to obtain proper precision from the test when the equipment is used for small quantities of wire and cable, which produce much smaller quantities of heat release and smoke obscuration."

* NFPA 259: "... NFPA 259 has traditionally been carried out on individual materials, and so the potential heat of a finished product like a cable would be calculated as the um of the contributions of each component, each contribution being the potential heat of the component multiplied by the mass fraction of that component in the cable. To produce such a measurement it would be necessary to disassemble the cable into its different components – insulation, jacket, shielding, rip cord and the like – and measure the potential heat of each component. *An obvious question is whether such a cumbersome procedure is necessary* ..." {Emphasis added, but statement comes verbatim from report}.

* Observations on NFPA 259: "One of the labs (Laboratory 2) had both more experience and more advanced equipment ..."

* Procedure for NFPA 259: "... The procedure followed was NFPA 259, Standard Test Method for Potential Heat of Building Materials, 1998 Edition, with modifications to the following sections: ... *This modification should be viewed provisionally since it so far has only been tested on 4-pair unshielded twisted pair (UTP) plenum cable*." {Emphasis added, but statement comes verbatim from report}

(iv) The oxygen bomb calorimeter test used to assess "limited combustible" classifications is severely flawed. NFPA 259 uses the oxygen bomb calorimeter as part of its testing to assess potential heat. The term "limited combustible" was developed for "building construction materials", with the intent of applying it to materials of construction of the plenum and not to cables. NFPA 90A defines "limited combustible" as follows:

"Limited-Combustible Material. A building construction material not complying with the definition of noncombustible material that in the form in which it is used, has a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg) where tested in accordance with NFPA 259, Standard Test Method for Potential Heat of Building Materials, and complies with (a) or (b):

(a) Materials having a structural base of noncombustible material, with a surfacing not exceeding a thickness of 1/8 in. (3.2 mm), that has a flame spread index not greater than 50; (b) Materials, in the form and thickness used, other than as described in (a), having neither a flame spread index greater than 25 nor evidence of continued progressive combustion, and of such composition that surfaces that would be exposed by cutting through the material on any plane would have neither a flame spread index greater than 25 nor evidence of continued progressive combustion. Materials subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmospheric condition shall be considered combustible."

The oxygen bomb calorimeter is a method for determining the theoretical (or complete or absolute) calorific energy (or heat of combustion), as opposed to the effective (or practical) values. The reason such instruments are used is to ensure that the correct value is chosen. As such they represent the following chemical equations for combustible fuels containing only carbon, hydrogen and oxygen:

$$C + O_2 = CO_2$$

$$4\,H + O_2 = 2\,H_2O$$

For hydrocarbon fuels: $- C\,H_2 - + O_2 = CO_2 + H_2O$

However, when building materials are more complex, because they contain other elements, there is a certain inconsistency in the equation and in the energy calculated.

1. Cl: Thus, for example, when PVC is burnt in an oxygen bomb, depending on the fraction of hydrogen atoms present, there will be different proportions of the following two equations:

$$(C_2\,H_3\,Cl)_n + 2.5\,n\,O_2 = 2\,n\,CO_2 + n\,H_2O + n\,HCl$$

$$(C_2\,H_3\,Cl)_n + 2.75\,n\,O_2 = 2\,n\,CO_2 + 1.5\,n\,H_2O + 0.5\,n\,Cl_2$$

where the two equations differ by 380 kJ/kg.

2. S: Combustion of materials containing sulphur also depends on the final product. Typically the combustion bomb generates sulphuric acid as the final sulphur containing product, while furnace combustion generates sulphur dioxide (with the sulphur less fully oxidized). Therefore, the convention in bomb calorimetry is to determine values of calorific value of fuels (including coal), by referring to the quantitative conversion to sulphur dioxide, and ignoring the conversion to sulphuric acid (or sulphur trioxide) that occurs, by using a conversion factor based on the sulphur content. Interestingly, gypsum (which is calcium sulphate dihydrate), is a building material containing sulphur. The typical fuel containing sulphur is coal. The difference between conversion to sulphur dioxide and sulphuric acid is 9410 kJ/kg.

3. N: Combustion of materials containing nitrogen also has a convention: the heat of convention is normally calculated assuming that all the nitrogen is converted into molecular nitrogen. However, that is not what happens in oxygen bomb calorimetry, where nitrogen oxides and nitric acid are actually formed. Thus, a correction is applied to account for the following equation:

$HNO_3 = 0.5\,H_2O + 0.5\,N_2 + 1.25\,O_2$, with a net heat of reaction of 1017 kJ/kg.

4. F: Combustion of materials containing fluorine is generally represented as ending in the formation of carbon tetrafluoride (CF_4) and of hydrogen fluoride (HF), in varying proportions. The equation is as follows:

$$C_a\,H_b\,O_c\,F_e + (a+b/4-c/2-e/4)\,O_2 + (n+1/2)*e*(1-x) - b/2)\,H_2O = (a-ex/4)\,CO_2 + + ex/4\,CF_4 + e(1-x)\,(HF) + e(1-x)\,n\,H_2O$$

where x is the fraction of fluorine atoms converted to CF_4 as opposed to converted to HF. The energy of the conversion of CF_4 to HF is approximately 192 kJ/kg. Moreover, fluorine materials will attack the walls of the bomb calorimeter.

5. Si: Compounds containing silicon are impossible to convert completely to their final oxidation product, which is silica (SiO_2), by conventional means because as burning proceeds, the material becomes covered by a layer of silica which prevents access of oxygen and leads to the formation of a residue. The only way to obtain a reliable result of heat of combustion of materials containing silicon (such as silicones) is by a method which combines the material with an organic fluorine compound (the value of which has been accurately assessed in advance) in rotating bomb containing also water and aqueous HF. This converts all the Si into fluorosilicic acid, and the results can then be calculated back.

6. P: Compounds containing phosphorus are exceedingly difficult to assess by oxygen bomb combustion calorimetry. There are four major problems: (1) various phosphorus acids with different energies of dilution are formed in various concentrations throughout the oxygen bomb, (2) the combustion products contain different types of phosphorus oxyacids, each one of which has a different heat of formation, (3) the burning compound gets covered by phosphorus oxides and acids, which inhibit further combustion and (4) the bomb calorimeter walls are attacked and metal phosphates are formed, so that the recommended wall materials should be corundum or gold, since Pyrex glass, quartz, stainless steel titanium, porcelain and platinum all suffered heavy weight losses. For example, depending on whether a rotating bomb or a static bomb is used, the fraction of pyrophosphoric acid formed varied from 10 to 18% and that of triphosphoric acid from 1 to 3%.

7. Auxiliary combustion material: When an auxiliary material is used for assessing the heat of combustion, a 1% error in the assessment of the heat of combustion of the auxiliary material (such as benzoic acid), which is typically used in the order of 20% energy loading, corresponds to a 5% error in the total energy/heat measured. Thus, at a value of 1500 kJ/kg that would be an error of 75 kJ/kg, and this would be a systematic error for that series of experiments.

8. Moisture content: the moisture content of the building material is critical, because the combustion reaction considered in

the oxygen bomb is that to convert to gaseous water. Thus, if a material contains water, the water will have reaction to vaporize the water content. Thus, results must be expressed as a function of the original moisture content for them to be valid. This matters, of course, for materials that absorb moisture when exposed to the atmosphere.

(Log #1570)

16- 370 - (830-2-Abandoned Cable): Accept in Principle
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-364
RECOMMENDATION: Add definition:

Abandoned Cable: Cable that is not terminated at both ends, not connected to equipment, or not identified for future use with a tag.

SUBSTANTIATION: Section 830.55(A) includes a requirement to remove abandoned cable but abandoned cable is not defined in this section. It is not believed that this is new material as the term "abandoned cable" was added. Also, the definition has been added to five other sections (725-2, 760-2, 770-2, 800-2, and 820-2). This comment provides consistency between sections of the code and assists the user in understanding terms used in the code.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to the panel action and statement on Comment 16-315.

(Log #1584)

16- 372 - (830-3(a)): Accept in Principle in Part
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-364
RECOMMENDATION: Revise text to read as follows:

Spread of Fire or Products of Combustion. Installations in hollow spaces, vertical shafts, and ventilation or air-handling ducts shall be made so that the possible spread of fire or products of combustion will not be substantially increased. Openings around penetrations through fire resistance-rated walls, partitions, floors, or ceilings shall be firestopped using approved methods to maintain the fire resistance rating.

Abandoned cables not intended for future use shall not be permitted to remain.

FPN: Directories of electrical construction materials published by qualified testing laboratories contain many listing installation restrictions necessary to maintain the fire-resistive rating of assemblies where penetrations or openings are made.

SUBSTANTIATION: This definition under the section entitled "Spread of Fire or Products of Combustion" is not consistent throughout the Code. This comment uses language from ROP 16-250 [850-52(B)] to provide a consistent requirement throughout the code.

The same comment is being made for the following sections:
640-3A (ROP 16-1a)
645-5D6 (ROP 12-106)
725-3B (ROP 16-80)
760-3A (ROP 16-144)
770-3A (ROP 16-176)
820-3A (ROP 16-313)
820-52 B (ROP 16-311)
830-58B (ROP 16-368)

PANEL ACTION: Accept in Principle in Part.

PANEL STATEMENT: The panel accepts in principle the statement regarding abandoned cables. Refer to panel action on Comment 16-397. This satisfies the submitter's concerns.

The current reference to 300-21 satisfies the balance of the comment, which is rejected. That portion of the comment repeats the text of 300-21.

16- 375 - (830-5(b)(2) (New)): Accept in Principle in Part

SUBMITTER: Marcelo M. Hirschler, GBH International

COMMENT ON PROPOSAL NO: 16-332

RECOMMENDATION: Revise text as follows:

830-5. Access to Electrical Equipment Behind Panels Designed to Allow Access

Access to equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).

a. New building construction (e.g. renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.

b. Buildings with existing cable systems. Where practicable, installation of cables shall comply with Section 300.11. Where impracticable to comply with Section 300.11, in those areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables less than 13 mm (0.5 in) in diameter, between access points in the ceiling. ~~cables less than 13 mm (0.5 in) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.~~

~~1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.~~

~~2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.~~

SUBSTANTIATION: The permission granted by the panel to install cables on suspended ceiling tiles should be rescinded. Neither cables nor any other item should be installed on top of a suspended ceiling tile. The support systems of suspended ceilings are not designed to resist any significant amount of weight without being deflected or broken.

This issue has been raised on Proposal 16-192 (log 1665) in negative comments by two panel members, Mr Egesdal and Mr Speer, who both correctly point out that suspended ceiling tiles are not intended to support the weight of electrical cables. Mr. Sandy Egesdal repeats his negative comment on this proposal.

The point made by the Technical Correlating Committee on proposal 16-38 that such use would constitute an exposed use of cables is an additional consideration to rejecting this part of the proposal.

PANEL ACTION: Accept in Principle in Part.

PANEL STATEMENT: The panel accepts the principle of permitting a limited number of cables to be installed in a fixed or hard ceiling. The panel rejects the balance of the submitter's recommendation including the limiting of the installation of cables in a suspended lay-in ceiling . The recommendation of Comment 16-375a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications cables in existing construction.

16- 377 - (830-6): Reject

SUBMITTER: Glenn W. Zieseniss, Crown Point, IN

COMMENT ON PROPOSAL NO: 16-332

RECOMMENDATION: Change the "Accept in Principle" to "Reject".

SUBSTANTIATION: I agree with Mr. Egesdal's and Mr. Speer's negative vote and comment on Proposal 16-192. This proposal is giving a "blanket okay for any type of ceiling tile to support the possible added weight of 3 cables of less than 1/2 in. in diameter on each ceiling tile. The proposal does not affirm that the ceiling tile industry was contacted of adding weight to lay on their product. This product is not part of the building structure, and is not designed to be suitable for supporting cables. I have seen ceiling tiles which look as if made of fiber glass insulation which has a finished surface on the exposed side of the ceiling. It is my belief that this ceiling tile would not accept additional weight upon it. I have contacted three ceiling tile companies or organizations on this proposal. They all suggested that their ceiling tiles are not to support additional weight. I have provided copies of my e-mail contacts.

NOTE: Supporting Material is available at NFPA Headquarters.

PANEL ACTION: Reject.

PANEL STATEMENT: The recommendation of Comment 16-375a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications cables in existing construction. The restrictions contained in Comment 16-375a limit both the number and size of wires and cables permitted on each ceiling panel, thereby controlling weight and accumulation so that cables can be easily moved aside to permit access. The submitter's concern about weight is addressed

by decreasing the size of the cable to 1/4 inch and limiting the number of cables to three per each 10 ft x 10 ft area.

(Log #864)

16- 378 - (830-6): Accept in Principle in Part
SUBMITTER: Larry F. Miller, National Electrical Manufacturers Association (NEMA)
COMMENT ON PROPOSAL NO: 16-332
RECOMMENDATION: The Panel shold continue to Accept the proposal in Principle but revise the Panel action text to read as follows:

830-6. Access to Electrical Equipment Behind panels Designed to Allow Access.

Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use or maintenance. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.

b.1. Installation of cables in suspended lay-in type ceiling spaces shall comply with 300.11.

2. Installation of cables in other than suspended lay-in type ceiling spaces shall comply with 300.11 where the space is accessible.

3.Where the ceiling is not the lay-in type, and the space is not accessible, three cables less than 13 mm (0.5 in.) shall be permitted to be installed unsupported by the building structure between access points or access panels.

~~Buildings with existing cabling systems.~~

~~Where practicable, installation of cables shall comply with Section 300.11. Where impracticable to comply with Section 300.11, cables less than 13 mm (0.5 in) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.~~

~~1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.~~

~~2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum three supported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.~~"

SUBSTANTIATION: We agree with Mr. Egedsal's and Mr. Speer's negative comments that suspended ceilings are not intended to support electrical wires or cables.

Section 300-11(a)(1) (wiring located within the cavity of a fire-rated floor-ceiling or roof-ceiling) allows an exception for wiring that has been tested as part of the fire-rated assembly. This proposal could compromise the fire-rating of the ceiling by overriding that requirement. The words "or maintenance" have been added because so much of the damage occurs in ceiling spaces as various trades perform maintenance.

The submitter states that he has submitted companion proposals for Articles 725 760, 770, 820 and 830. If each of these articles will allow three cables per ceiling tile, this could result in a total of 18 cables per ceiling tile, which appears to be approaching the "excessive accumulation" the submitter agrees could be a hazard. Limiting the size and quantity of cable permitted to be fished in non-lay-in ceiling spaces will help control the weight of cable (combined with that permitted in the other articles referenced above) on these ceilings.
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: The panel rejects the recommended addition of the word "maintenance." The term "normal building use" includes "maintenance." The balance of the recommendation is accepted in principle. Refer to the recommendation and substantiation on Comment 16-375a.

(Log #965)

16- 379 - (830-6): Accept in Part
SUBMITTER: Palmer Hickman, Royersford, PA
COMMENT ON PROPOSAL NO: 16-332
RECOMMENDATION: Reject Proposal 16-332 as amended by Code Panel 16. Accept the Proposal as submitted by Mr. Brunssen.
SUBSTANTIATION: I recommend reconsideration of Code-Making Panel 16's action on this proposal. The proposed 830.6(B)(2) would now permit three cables to be installed on the tiles of a suspended ceiling, without providing any technical substantiation for this allowance.

I understand that this proposed allowance of ceiling support only applies to buildings with existing cabling systems where it is "impracticable" to comply with 300-11. Impracticability does not provide technical substantiation to allow a ceiling assembly that has not been evaluated to support the potential additional load of three cables on each and every ceiling tile.

I am aware that Chapter 8 is independent of other chapters except where specifically referenced therein. Panel 16 has referenced 300-11, and Code-Making Panel 3 is on record reaffirming their prohibition of ceiling assemblies being used beyond the manufacturers design parameters in the Panel Statement to Comments 3-53 and 3-57 of the 1998 ROC, and Proposal 3-68 of the 2001 ROP. In the latter reference, Code-Making Panel 3 states: "The panel reaffirms its position that an independent means of support shall be provided for all wiring, not just branch circuit wiring. . .".

The substantiation provided by Mr. Brunssen for his proposal does not support the proposed change as amended by Code-Making Panel 16. He claims that "a limited amount of cabling laid directly on a suspended ceiling is permitted..." without stating where this permission is given. The entire substantiation of the submitter seems contrary to the action of the panel. I am not sure he would recognize the end result as the proposal he made. Mr. Brunssen begins his substantiation by stating that "Section 830-6 may be misinterpreted to mean that cables may not be placed directly on suspended ceilings." He notes that the 1999 NEC Handbook "Figures 830-2 and 830-3 lead the reader to conclude that no cables are permitted to rest directly on the suspended ceiling." The submitter also stated Code-Making Panel 16 responded to a proposal to Article 725 (1992 TCD Comment 16-18) that the proposed requirement "...would still allow some cabling of a limited quantity above the ceiling tile, but not to an excessive amount." Note the words "above the ceiling tile", not on the ceiling tile. I feel these examples are not misinterpretations, but rather correct interpretations, and a case to reject this proposal as amended by Code-Making Panel 16.

In conclusion, I respectfully disagree with the Panel Action on this Proposal. I find no technical substantiation to warrant such a dramatic change. Mr. Brunssen presented a well-researched proposal addressing access, not support. The substantiation of the submitter does not support this change as amended, nor does the Panel Statement.
PANEL ACTION: Accept in Part.
PANEL STATEMENT: The panel accepts the portion of the comment to retain Section 830.6, and rejects the portion of the comment to reject Proposal 16-332. Refer to the recommendation and substantiation on Comment 16-375. Also refer to the panel action and statement on Comment 16-377.

(Log #1154)

16- 380 - (830-6): Accept in Principle
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-332
RECOMMENDATION: Continue to accept in principle.
SUBSTANTIATION: Panel 16 should continue to accept in principle as it provides a reasonable and safe solution to placing a limited number of signaling and communications wires and cables in existing construction. The restrictions contained in the proposed change limit both the number and size of wires and cables permitted on each suspended ceiling panel. In this manner additional weight, as well as an accumulation of wires and cables that would otherwise restrict access above suspended ceiling panels, is controlled and limited. The limited number of cables permitted can easily be moved aside to permit access. Some concern has also been expressed that cables placed directly on the ceiling panels would degrade the fire rating of the ceiling. The

suspended ceiling, part of a membrane that is intended to retard fire from spreading into the ceiling cavity, would be unaffected in its ability to retard the spread of fire by a limited number of wires and cables resting on top of the panels. This is a companion comment and is intended to correlate with comments on Proposals 16-38, 16-112, 16-159, 16-192, and 16-278.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to the substantiation on Comment 16-375a. This action meets the intent of the submitter.

(Log #1162)

16- 381 - (830-6): Accept in Principle
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-332
RECOMMENDATION: Revise as follows:
830-6. Access to Electrical Equipment Behind Panels Designed to Allow Access. Access to electrical equipment shall not be denied by an accumulation of wires and cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. Access to electrical equipment behind ceilings designed to allow access shall comply with (a) or (b).
a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11.
b. Buildings with existing cabling systems. Where practicable, installation of cables shall comply with Section 300-11. Where impracticable to comply with Section 300-11, cables less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.
1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.
2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of ~~any one~~ each ceiling tile, i.e., up to three wires and cables are permitted to lay on a ceiling tile. The cables shall be run parallel to the ceiling grid.
SUBSTANTIATION: Proposed Section 830-6(b)(2) as presently written in Proposal 16-332, panel action, is confusing and could be interpreted as permitting a total of only three unsupported wires and cables above a suspended ceiling. The intent of the panel was that up to a maximum of three unsupported wires and cables may be routed across each and every ceiling tile. The revision proposed in this comment clarifies and accomplishes the intent of the panel. This is a companion comment and is intended to correlate with comments on Proposals 16-38, 16-112, 16-159, 16-192, and 16-276.
PANEL ACTION: Accept in Principle.

(Log #CC1607)

16- 375a - (830-6, 8, 9, 10, 11): Accept
Note: The Technical Correlating Committee directs that the references to Articles 640 and 650 be deleted because the panel did not accept similar requirements in those articles. The Technical Correlating Committee also directs that the FPN which contains a mandatory requirement be deleted to comply with the NEC Style Manual.
SUBMITTER: CMP 16
COMMENT ON PROPOSAL NO: 16-332
RECOMMENDATION: Renumber current Section 830-8 as 830-9.
Renumber current Section 830-9 as 830-10.
Renumber current Section 830-10 as 830-11.
Renumber current Section 830-11 as 830-12.
Retain the existing 1999 code text for Section 830-6 (unmodified).
Add new Section 830.8 to read as follows:
830.8 Installation of Circuits.
Network-powered broadband communications systems shall be installed in compliance with A or B.
A. New Ceiling Construction. The installation of cables in new ceiling construction shall comply with Section 300-11.
B. Existing Ceilings.
1. Fire-Rated Ceilings. The installation of cables in the cavity of an existing fire-rated ceiling assembly shall comply with Section 300-11.
2. Non-Fire-Rated Ceilings. For installations in the cavity of an existing non-fire-rated ceiling assembly, cables less than 6 mm (0.25 in) in diameter shall be permitted to be installed unsupported from the building structure in accordance with the following:
a. Fixed or Hard Ceilings. In areas having fixed or hard ceilings with access points or access panels, a combined total of three cables from Articles 640, 650, 725, 760, 770, 800, 820 and 830, shall be permitted to be placed between access points or access panels in the ceiling. Additional cables shall be installed in accordance with 300.11.
b. Suspended Lay-In Ceilings. In areas having suspended lay-in ceilings, in any 3 m by 3m (10 ft. x 10 ft) ceiling area, a combined total of three cables from Articles 640, 650, 725, 760, 770, 800, 820 and 830, shall be permitted to be installed directly on the ceiling grid. Additional cables shall be installed in accordance with 300.11.
FPN. Cables of all types are included in the total limit of three cables, not three cables from each article.
SUBSTANTIATION: Proposal 16-332 was accepted in principle to permit the installation of unsupported cables under limited conditions. Proposal 16-332 text, however, was too broad and unclear. The text of this comment clarifies the original intent. The new text includes requirements to comply with Section 300.11. Permitted installation conditions will not compromise the integrity of fire-rated ceilings. For non-fire-rated ceilings, the permitted

relief from Section 300.11 is limited to very specific conditions. Section 830.6 is not being modified because the accessibility requirements should remain.

The sections have been renumbered so that they appear in a logical order.

PANEL ACTION: Accept.

(Log #745)

16- 385 - (830-6(b)): Accept in Principle in Part
SUBMITTER: Richard P. Owen, City of St. Paul, Electrical Inspection
COMMENT ON PROPOSAL NO: 16-332
RECOMMENDATION: Replace (b) of the proposal with the following text:

(b) Buildings not Covered Under (a) Above. In areas having ceilings with access points or panels and having 900 mm (3 ft) or less vertical clearance above the ceiling, it shall be permissible to fish a maximum of 3 cables, each less than 13 mm (0.5 in.) in diameter, between access points in the ceiling.

SUBSTANTIATION: The Technical Correlating Committee directed Panel 3 Chair Raymond Weber to form a Task Group to review these proposals and to submit the results as comments to Panel 16. Task Group 3-16, consisting of Chair Weber, members Steven Speer; Lee Hewitt; Richard Owen and Ron Maassen held a conference call on October 3, 2000 and developed the above language as a comment. The Task Group was concerned with allowing unsupported cabling above suspended ceilings, since companion proposals for Articles 725, 760, 770, 800, 820 and 830 would also allow this limited cabling without support. The possible accumulation of cable allowed by all these articles would be excessive and would both limit access to a ceiling and conflict with Section 300.11. Rewording of (b) also eliminated the unenforceable terms "practicable" and "impracticable" as directed by the Technical Correlating Committee.
PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: The panel rejects the specific limitations in the comment but accepts the principle of permitting a limited number of cables. The recommendation of Comment 16-375a provides a reasonable, safe, and practical solution to placing a limited number of unsupported network-powered broadband communications cables in existing construction.

(Log #1259)

16- 386 - (830-6(b)(2)): Reject
SUBMITTER: J. Paul Spinn, USG Research & Technology Center
COMMENT ON PROPOSAL NO: 16-332
RECOMMENDATION: Delete the following text:

In areas having suspended lay in ceiling, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.

SUBSTANTIATION: By allowing a maximum of three unsupported cables on top of any one (or more) ceiling tiles, the fire-rating of the assembly and the Class A surface burning characteristic requirement, which includes flame spread and smoke development, could be jeopardized. By decreasing the fire-rating of the plenum assembly and the surface burning characteristic of the ceiling tile, the life safety of the occupants can be negatively affected. By rejecting this proposal, these problems can be eliminated.

To substantiate the comment made for the proposal, four key points are provided:

[1] For a fire rated floor/ceiling or roof/ceiling assembly, placement of unsupported cables on top of any one ceiling tile or a row of ceiling tiles could invalidate the fire-rating for a particular assembly. The rationale for this argument are:
(a) The weight of the cables could cause premature tile fallout leading to an early failure of the assembly, which is tested in accordance with NFPA 251 or ASTM E 119.
(b) The increased heat of combustion associated with the cable jackets, which commonly use plastics, will add to the total fire load of an assembly. As the total fire load increases for an assembly, the fire endurance of the assembly will decrease, which could jeopardize an assembly's fire-rating.

[2] For a Class A ceiling, placement of unsupported cables on the ceiling can effect flame spread and smoke development performance and jeopardize the required Class A rating for the ceiling tiles. The rationale for this argument are:
(a) The flame spread will increase due to the increased total heat load, which is caused by the plastic on the cable jacket.
(b) The smoke development will increase due to the cable jackets, which are usually plastic such as PVC or CPVC.

[3] The placement of unsupported cables on top of any one or more ceiling tiles presents potential life safety issues for occupants due to the decreased fire-rating of the floor/ceiling or roof/ceiling or an increase in the ceiling surface burning characteristics.

[4] Placement of unsupported cables on top of any one ceiling tile or a row of ceiling tiles would increase ceiling tile sag due to increased weight of the cables on the ceiling tiles, and would impair the accessibility of the ceiling plenum.

PANEL ACTION: Reject.
PANEL STATEMENT: The recommendation of Comment 16-375a provides a reasonable, safe, and practical solution to placing a limited number of unsupported signaling and communications cables in existing construction. The restrictions contained in Comment 16-375a limit both the number and size of cables permitted on each ceiling panel, thereby controlling weight and accumulation so that cables can be easily moved aside to permit access. The submitter's concern about weight is addressed by decreasing the size of the cable to 1/4 inch and limiting the number of cables to three per each 10 ft x 10 ft area. The revised text precludes the installation of cables in all fire-rated ceiling assemblies.

(Log #1160)

16- 387 - (830-7): Reject
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-333a
RECOMMENDATION: Delete 830-7 and incorporate the information in 830-6 as follows:

830-6. ~~Access to Electrical Equipment Behind Panels Designed to Allow Access.~~ Mechanical Execution of Work. Network-powered broadband communications circuits and equipment shall be installed in a neat and workmanlike manner. Access to electrical equipment shall not be denied by an accumulation of ~~wires and~~ cables that prevents removal of panels. Cables shall be installed in such a manner that the cable will not be damaged by normal building use. ~~Access to electrical equipment behind ceilings designed to allow access~~ Cables installed exposed shall comply with (a) or (b).

a. New building construction (e.g., renovation, remodeling, new spaces). Installation of cables shall comply with Section 300.11. Cables shall be supported by structural components of the building. Such cables shall be attached to structural components at intervals not exceeding 1.52 m (5 ft) and within 305 mm (12 in.) from every cabinet, box, or fitting by straps, staples, hangers or similar fittings designed and installed so as not to damage the cable. The installation shall also conform with Section 300-4(d).

b. Buildings with existing cabling systems. Where practicable, installation of cables shall comply with ~~Section 300-11~~ 830-6(a) Where impracticable to comply with ~~Section 300-11~~ 830-6(a) cables less than 13 mm (0.5 in.) in diameter shall be permitted to be installed unsupported by the building structure in accordance with 1 or 2.

1. In areas having ceilings with access points or access panels, it shall be permissible to fish a maximum of three cables between access points in the ceiling.

2. In areas having suspended lay-in ceilings, it shall be permissible to install a maximum of three unsupported cables on top of any one ceiling tile. The cables shall be run parallel to the ceiling grid.

SUBSTANTIATION: This is a companion comment and is intended to correlate with similar comments on Proposals 16-39, 16-115, 16-159a, 16-192a, and 16-276a. Sections 830-6 and 830-7 actually address the same issue, the mechanical execution of work. Accessibility behind panels designed to allow access is really an "execution of work" issue. Additionally, the Technical Correlating Committee has identified a potential conflict between the panel action on Proposals 16-38 and 16-39, that would also result here in 830. This comment editorially combines 830-6 and 830-7 into a single Section 830-6 requiring attachment to the building structure of exposed cables and conductors and, where impracticable to do so, permits a limited number of cables of specified maximum size to be placed on suspended ceiling tiles. It accommodates the intent of both proposals that cables should be supported by the building structure, but in extenuating circumstances in existing construction, a limited number and weight of cables may be placed on a suspended ceiling. Further, in the first paragraph of 830-6, the phrase "wires and" is deleted as network-powered broadband circuits are provided via cable and not wire.
PANEL ACTION: Reject.
PANEL STATEMENT: The sections should not be combined. Refer to the recommendation and substantiation for Comment 16-375a where these recommendations are addressed.

SUBMITTER: Dan Leaf, Palmdale, CA
COMMENT ON PROPOSAL NO: 16-336
RECOMMENDATION: Accept in Part revised, and relocate after (d):

"except that overhead (aerial) cable shall be permitted to be attached to the exterior of a raceway-type mast intended for the attachment and support of such cables."

SUBSTANTIATION: The function and type mast is specified to provide the same wording as that in Panel Action for Proposal 16-314.
PANEL ACTION: Reject.
PANEL STATEMENT: The panel is unclear as to the change intended by the submitter in both the proposal and comment.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:
AFFIRMATIVE: 21
COMMENT ON AFFIRMATIVE:
TODD: The power service mast interface between NEC and NESC wiring does not need NEC ruling on attachments other than power conductors.

The submitter's comment is rejected for these reasons:

1. Panel 4 has continued to reject any attachments other than the power service conductors in article 230-28.

2. UL will not list this mast with unknowns of utility NESC span lengths, conductor loading levels (i.e., ice, wind, etc.) and multiple point sub-attachments, such as CATV and telephone service drop cables.

3. The electric utility industry has safety and subsequent liability concerns with power conductors on multiple attachment masts. This concern relates to the increased risk of snagging of the nonpower attachments and tearing down the power conductors.

This interface concern should be resolved between local power utility and telecommunication companies, not in the NEC. It is in the interest of fire and public safety to keep the power service mast for the exclusive safe environment of power conductors.

(See NEC Panel 16 statement to Proposal 16-202 from the October, 2000 Report on Proposals - ROP.)

(Log #617)

16- 391 - (830-10(j)): Accept in Principle
SUBMITTER: Steven C. Johnson, Time Warner Cable
COMMENT ON PROPOSAL NO: 16-344
RECOMMENDATION: Reject the proposal to prohibit use of service masts for drop attachments.
SUBSTANTIATION: There is no reason to force a homeowner to install a separate mast to accommodate communications (telephone, CATV) service drops wherever the service mast can be listed to do so. An arbitrary prohibition of attaching to electrical masts is not reasonable. Where the mast can be shown to support additional attachments without creating a safety hazard, these attachments should be allowed. Reasonable qualifications would include the ability to support the weight (with ice loading) and not damage the mast or structure, ability to maintain proper clearance, etc.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to panel action and comment on Comment 16-392.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:
AFFIRMATIVE: 16
NEGATIVE: 5
EXPLANATION OF NEGATIVE:
DORNA: See my explanation of negative vote on Comment 16-271.
KAHN: The comments should be rejected and the original Panel Action to Reject Proposal 16-344 should be sustained.
Code-Making Panel 4 has rejected the Proposal and that panel has primary jurisdiction. In their Panel Statement, they state: "... that they do not believe that the listing of the product will adequately address the personnel issues that are created by the co-mingling of the different systems on a common mast. Issues such as loading can be addressed by the proposed listing, however personnel safety cannot be assured regardless of the listing criteria." I agree with their assessment.
A task group of Code-Making Panel 4 and Code-Making Panel 16 members as suggested in the Panel Statement should be formed to study the problem further if the Technical Correlating Committee deems it advisable.
MANGAN: See my explanation of negative vote on Comment 16-271.
SPEER: See my explanation of negative vote on Comment 16-271.
TODD: See my explanation of negative vote on Comment 16-155.

(Log #1146)

16- 392 - (830-10(j) (New)):
Note: The Technical Correlating Committee directs that this comment be reported as "Reject" to correlate with the action on Proposal 4-73 and Comment 4-51.
SUBMITTER: James E. Brunssen, Telcordia Technologies, Inc.
COMMENT ON PROPOSAL NO: 16-344
RECOMMENDATION: Accept the proposal.
SUBSTANTIATION: This is a companion comment to my comment on Proposal 4-73 wherein it was proposed to revise Section 230-28 to permit communications wires and cables to be attached to a service mast that is listed for the purpose. Code-Making Panel 4 has been asked to reconsider their rejection of Proposal 4-73, based on the panel statement that Code-Making Panel 4 does not "believe" listing will adequately address the personnel safety issues. Code-Making Panel 4's position is contrary to both the industry and NEC accepted method to ensure the safety of wiring, cable, and equipment when used for its intended application, that of listing by a Nationally Recognized Testing Laboratory (NRTL). Listing will ensure that the service mast can adequately support multiple attachments while providing for the safety of power, communications, and CATV technicians who must access the service mast. Code-Making Panel 16 stated that detailed design and installation requirements are not defined. This is the purpose of listing - to establish that a product will be safe when used as intended. It is unreasonable to arbitrarily prohibit attaching to the electric service mast and cause the homeowner to bear the cost of a separate mast for communications. When the mast is listed and installed properly for its intended use, it will be capable of safely supporting, and safely permitting access to, multiple attachments. Code-Making Panel 16 should accept Proposal 16-281 based on the merits of the submitter's original substantiation, contingent upon the action of Code-Making Panel 4.
Note also companion comments to Proposals 16-202 and 16-344.
PANEL ACTION: Accept.
PANEL STATEMENT: CMP 16 understands that CMP 4 has primary jurisdiction over requirements associated with the power service mast. A companion comment has been submitted to CMP 4 to allow relief for the attachment of communications cables to the power service mast. Should CMP 4 continue to reject the proposal, CMP 16 requests that the Technical Correlating Committee assign a task group consisting of members of both panels to review the issues.

(Log #1120)

16- 394 - (830-40(a)(4)): Reject
SUBMITTER: Steven C. Johnson, Time Warner Cable
COMMENT ON PROPOSAL NO: 16-357
RECOMMENDATION: Reject Proposal 16-357.
SUBSTANTIATION: 1. The distance between entrances for different services is practically limited to 100 feet for most installations which corresponds to 0.3 ohms for 14 AWG solid copper conductor and 0.05 ohms for 6 AWG solid copper conductor. Neither resistance is significant. The new 830-40(a)(4) proposed would mandate placing an additional electrode wherever the distance between the grounding terminal for communications cables and the electrical service ground is greater than 20 feet. The additional electrode would not significantly decrease resistance to ground nor increase safety.
2. The practical difference between the existing code and the proposed change is that the grounding conductor size is increased to 6 AWG every time the 20-foot distance rule is violated. This difference results in 0.25 ohm difference in the extreme case of 100 feet grounding conductor run. The difference is usually significantly less than 0.25 ohms since the distance is usually less than 100 ft and the size of the grounding conductor is normally larger than 14 AWG. The requirement for approximately equal ampacity for cable sheath and grounding conductor in 830-40(3) results in larger grounding conductor than 14 AWG in most cases.

3. The proposal provided no technical justification for the quantified 20-foot limitation and no demonstrated improvement in safety. No problems are cited and no incidents of damage or harm are presented that are the result of present installation and bonding practices.
4. The 20 foot rule is not always practical to maintain. The new proposal would result in a backlash from homeowners whenever an additional electrode is to be placed and 6 AWG wire to be used to bond it to the existing electrode system.

PANEL ACTION: Reject.
PANEL STATEMENT: The panel's intent is to limit the potential difference between power and communications circuits during lightning events.

That potential difference is generally a function of conductor inductance (L), which increases in direct proportion to conductor length, and the rate of rise of the current (di/dt). This proposal addresses that issue, encourages short cable, shield grounding conductors, provides guidance as to a reasonable maximum length, and provide an alternative where it is not practicable to meet the maximum length (20 ft) restriction. The proposed length restriction is limited to one- and two-family residences as it is such installations that are more likely to have diverse power and communications entrances and experience lightning-related problems (urban/suburban environment with a fewer elevated structures and extensive buried metallic objects).

16- 395 - (830-40(a)(4)): Reject
SUBMITTER: Andy Scott, National Cable Television Association
COMMENT ON PROPOSAL NO: 16-357
RECOMMENDATION: Reject Proposal 16-357.
SUBSTANTIATION: The Cable Television industry urges the NFPA to reject this proposal. These proposals have no technical merit and no demonstrated improvement in safety. To our knowledge, no incidents of harm or damage that were the result of existing installation and bonding practices have been documented to support such a change in existing practice.

The practice within the cable industry is to maintain grounding conductors as short as practicable. In the majority of installations, the distance between entrances for different services is limited to approximately 100 ft. This distance corresponds to 0.3 ohms for 14 AWG solid copper conductor and 0.05 ohms for 6 AWG solid copper conductor. Neither resistance is significant. Notwithstanding the additional increase in installation cost to the customer, the 20 ft rule cannot be practically maintained, and would result in a negative reaction from homeowners whenever an additional electrode is to be placed and 6 AWG wire to be used to bond it to the existing electrode system.

16- 398 - (830-55(a)): Accept in Principle
SUBMITTER: Marcelo M. Hirschler, GBH International/Rep. Plenum Cable Association and Fire Retardant Chemicals Assoc.
COMMENT ON PROPOSAL NO: 16-364
RECOMMENDATION: Continue accepting this proposal in principle, by retaining the phrase: "Abandoned cables, not intended for future use shall not be permitted to remain."
SUBSTANTIATION: There is a potential for increased fire hazard or fire risk when any cable, irrespective of whether it is or is not limited combustible, remains as fuel load unnecessarily once it has been taken out of use. Materials that are limited combustible can also burn (i.e., they are not noncombustible) and also increase the fire load. Furthermore, all abandoned cables can also affect the safety of plenums because of their weight. There is, thus, no justification for permitting any cable to remain in a plenum once it is abandoned and not intended for future use.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-397.

(Log #303)

16- 400 - (830-55(a)-Abandoned Cable): Accept in Principle
SUBMITTER: Gerald Lee Dorna, Belden Wire & Cable Co.
COMMENT ON PROPOSAL NO: 16-364
RECOMMENDATION: A definition of "Abandoned Cable" is needed here to clarify the situation. It is probably more appropriate that this definition goes under 830-2 "Definitions." The definition that needs to be added is as follows:

Abandoned Cable. Cable that is neither terminated at equipment, nor identified for future use with a tag.

This is the same definition that we accepted in Proposal 16-273.
SUBSTANTIATION: To make this article correspondent with Articles 725, 760, 770, 800 and 820, the above wording should be used. This will also clarify for the authority having jurisdiction exactly what is an "Abandoned Cable."
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: Refer to panel action and statement on Comment 16-315.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 21
VOTE ON PANEL ACTION:
AFFIRMATIVE: 21

(Log #1253)

16- 401 - (Table 830-58): Accept in Principle
SUBMITTER: Irving Mande, Edwards Systems Technology (EST)
COMMENT ON PROPOSAL NO: 16-366
RECOMMENDATION: Accept this proposal.
SUBSTANTIATION: This Comment should also be accepted if my Comment for Proposal 16-223 is accepted.
PANEL ACTION: Accept in Principle.
Delete MPP, MPR, MPG and MP from Table 830-58 and delete the FPN below the table.
PANEL STATEMENT: The application of multipurpose cables have been retained but including multipurpose cables in Table 830-58 is not necessary because the table includes communications cables and Article 800 provides for substituting multipurpose cables for communications cables. The original proposal had an option and the panel action has accepted the option of deleting the FPN.

(Log #1585)

16- 404 - (830-58(b)): Accept in Principle in Part
SUBMITTER: Wayne G. Carson, Carson Assoc. Inc.
COMMENT ON PROPOSAL NO: 16-368
RECOMMENDATION: Revise text to read as follows:

Spread of Fire or Products of Combustion. Installations in hollow spaces, vertical shafts, and ventilation or air-handling ducts shall be made so that the possible spread of fire or products of combustion will not be substantially increased. Openings around penetrations through fire resistance-rated walls, partitions, floors, or ceilings shall be firestopped using approved methods to maintain the fire resistance rating.

Abandoned cables not intended for future use shall not be permitted to remain.

FPN: Directories of electrical construction materials published by qualified testing laboratories contain many listing installation restrictions necessary to maintain the fire-resistive rating of assemblies where penetrations or openings are made.
SUBSTANTIATION: This definition under the section entitled "Spread of Fire or Products of Combustion" is not consistent throughout the Code. This comment uses language from ROP 16-250 [850-52(B)] to provide a consistent requirement throughout the code.

The same comment is being made for the following sections:
640-3A (ROP 16-1-a)
645-5D6 (ROP 12-106)
725-3B (ROP 16-80)
760-3A (ROP 16-144)
770-3A (ROP 16-176)
820-3A (ROP 16-313)
820-52B (ROP 16-311)
830-3A (ROP 16-364)

CHAPTER 9 — TABLES

(Log #763)

8- 98 - (Chapter 9 Table 4): Accept
SUBMITTER: Richard E. Loyd, Perryville, AR
COMMENT ON PROPOSAL NO: 8-455
RECOMMENDATION: I urge the panel to revisit this proposal and accept it as written based on the negative comments.
SUBSTANTIATION: Adding the word "nominal" makes the user aware that the measurements listed in the table may vary slightly due to allowable tolerances. I agree with the negative comments. Sheet materials used to manufacture conduit and tubing have a small variation in the thickness that is unavoidable. This will have a slight effect on the I.D. measurement since the I.D. is derived by subtracting 2 times the wall thickness from the (nominal) O.D. Technically, since the standard does allow for these tolerances the term "nominal" is appropriate.
PANEL ACTION: Accept.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 14
VOTE ON PANEL ACTION:
AFFIRMATIVE: 12
NEGATIVE: 2
EXPLANATION OF NEGATIVE:
KENDALL: In the case of conduit and tubing, the word "nominal" applies to "Trade Size". There are dimensions shown on internal diameter that are based on either average, minimum or maximum wall thickness and/or outside diameter. Changing the heading will not harmonize these dimensions. Since all of these dimensions are within the required product standards and that the heading does not indicate a minimum, maximum or average, a safety issue is not present. As the submitter states, nothing changes from past practices with or without this change. The change will only introduce confusion among the inspection and electrical contractors.

I favor and recommend that a NEC Task Group be developed to review the internal diameter used in these tables and harmonize on which inside diameter is to be used. The column than can be labeled "Maximum, Minimum or Average".

See my explanation of negative vote on Comment 8-98a.

LILLY: I agree with Mr. Kendall. The word "nominal" does apply to trade size and not to the actual internal diameter. A task group should be given the responsibility of developing a proposal to harmonize the diameters and establish a column heading utilizing "Minimum", "Average", or "Maximum".
COMMENT ON AFFIRMATIVE:

(Log #CC801)

8- 98a - (Chapter 9, Table 4): Accept
SUBMITTER: CMP 8
COMMENT ON PROPOSAL NO: 8-453
RECOMMENDATION: Revise Table 4 to read as shown on the pages 687 through 692:
SUBSTANTIATION: This action corrects errors found in the conversion to metric dimensions and adds a new column for 60% raceway fill (Comment 8-99). The panel directs staff to correct title errors (2002 NEC Draft) in Flexible Metal Conduit and Rigid Metal Conduit.
PANEL ACTION: Accept.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 14
VOTE ON PANEL ACTION:
AFFIRMATIVE: 11
NEGATIVE: 3
EXPLANATION OF NEGATIVE:
KENDALL: This comment should be put on "hold". I agree with Wayne Lilly and the IAEI negative statement on Comment 8-98a. I believe a Task Group should be developed to ensure that the correct values be used in this table. The 60 percent column can be added at that time (Comment 8-99) and the term "Nominal" (Comment 8-98) can be decided upon by the same Task Group.

LILLY: The action on this comment should be to hold with a recommendation that a task group be appointed to analyze the proposed Table 4, verify the numbers contained are correct, establish and place in the code a means by which the numbers are verifiable, and correlate Table 4 with Appendix C. This comment was generated by Code Making Panel 8. It contains the present Table 4, a new 60 percent column for nipple fill, and a new metric column for each of the present columns and the new 60 percent column. Additionally, there are several changes to the present Table 4 numbers. All of the new numbers are new material and have not had the benefit of public review.

The current Table 4 and Appendix C are the result of a NEMA submitted proposal. That proposal expanded Table 4 so that it provided fill percentages and raceway diameters for each trade size of each of the circular raceway types. The previous Table 4 only provided for a single diameter and raceway fill percentages for each raceway trade size.

This comment was generated to correct errors in the fill percentage numbers for the raceways. There was no information provided to indicate why the numbers in the existing Table 4 are wrong. What makes the numbers in the proposed Table 4 more correct than those in the existing Table 4?

The panel was not provided any math to indicate how the calculations were determined. For example, was pi used as 3.141 or 3.142? How many places to the right of decimal were used? What method was used to round up or round down, if any? Were the methods utilized the same as those utilized by NEMA for the original proposal? If the method used was not the same as that used by NEMA then the numbers in Appendix C may be compromised and the numbers being changed in Table 4 may not reflect the original intent.

There was no correlation made with the proposed changes to the 40 percent column and Appendix C. For example, the maximum number of number 14 THHN conductors permitted in 2-inch Type A LFNC using the current Table 4 40 percent fill and as found in Table C6 of Appendix C is 137. The comment would permit 138 such conductors. It is important that a comparison be made to maintain the correctness of Appendix C. Although this is a very small change, the panel should not knowingly create incorrect code.

ROWE: The information contained in the current NEC, (NFPA 70-1999) is the product of a Joint Task Group effort, which combined members from Code-Making Panel 6 and Code-Making Panel 8. I am not aware of the method that Task Group used to calculate the information contained in the 1999 NEC, nor, am I fully understanding of the method used to prepare the calculations proposed to be included in the 2002 NEC, contingent on panel acceptance of this panel generated comment, (8-98a).

I believe it is a mistake to further amend this section the NEC until there is a full understanding and acceptance of the method and resultant calculations advocated by this comment.
COMMENT ON AFFIRMATIVE:

BERMAN: Discussion of Chapter 9, Table 4 and Appendix C has resulted in some confusion regarding the source and accuracy of the information on raceway internal diameters and wire fills. To examine these values and also to help maintain consistency in performing wire fill calculations, it is recommended that a Task Group be convened.

DAUBERGER: There seems to be some confusion regarding the wire fill information that was provided. Rather than include information that may not be accurate, I agree with the recommendation of convening a Task Group to review this information before we include it in the Code.

LOYD: I believe the technical committee was remiss in not clarifying the method used to determine that this new table contained errors, and to explain how many decimals were used in developing the corrected tables. Annex C was not reviewed for corrections. I would suggest that a Task Group of Code-Making Panel 8 members be formed to complete this work prior to the 2005 NEC development.

(Log #1710)

8- 99 - (Chapter 9 Table 4): Accept in Principle
SUBMITTER: Robert White, E Lansing, MI
COMMENT ON PROPOSAL NO: 8-456
RECOMMENDATION: Revise text as follows:

Add 60 percent column to Table 4 in Chapter 9, to aid in determining conduit fill for nipples. Values are included on the following revised Table 4 on pages 693 through 696:
SUBSTANTIATION: Nipples are frequently used in the field and there needs to be a quick, convenient way to determine maximum fill.
PANEL ACTION: Accept in Principle.
PANEL STATEMENT: See panel action and statement on Comment 8-98a.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 14
VOTE ON PANEL ACTION:
AFFIRMATIVE: 12
NEGATIVE: 2

EXPLANATION OF NEGATIVE:
KENDALL: This comment should be put on "hold". See my explanation of negative vote on Comment 8-98a.
LILLY: The action on this comment should be hold with a recommendation that a task group be appointed to analyze the proposed 60 percent fill numbers to verify their correctness with the method used to determine the original numbers in Table 4. Some of the items that need to be verified include whether pi was utilized as 3.141 or 3.142, how many places to the right of the decimal place were employed, and what method, if any, was used for rounding up or down. This is new material that has not had the benefit of public review.
See my explanation of negative vote on Comment 8-98a.
COMMENT ON AFFIRMATIVE:
DAUBERGER: See my comment on affirmative vote on Comment 8-98a.
ROWE: I believe that this panel action should have been "accept" rather than "accept in principle". This material is an important addition to the NEC and inclusion of this material should not be contingent on the acceptance of panel generated Comment 8-98a.

(Log #1558)

6- 83 - (Chapter 9 Table 5): Accept in Part
SUBMITTER: Ravindra H. Ganatra, Alcan Cable
COMMENT ON PROPOSAL NO: 6-212
RECOMMENDATION: This comment is prepared as requested by the Chair of Code-Making Panel (CMP) 6 and in consultation with the Chair of CMP 8 to address the Technical Correlating Committee (TCC) Comment on Proposals 6-212 and 8-458 (identical proposals reviewed by CMP 6 and CMP 8 for their respective jurisdictions).

Recommendation 1: CMP 6 recognizes and agrees with TCC observation that CMP 6 has accepted another proposal (6-202) that deletes Type AF referenced in these two proposals.

Recommendation 2: It is recommended that CMP 8 accept Item 5 of the proposal and reverse its decision.
SUBSTANTIATION: No substantiation is required for Recommendation 1.

Substantiation for Recommendation 2:

CMP 8 Statement provides this reasoning for their action: "By reducing the required insulation thickness for these wire types without changing the designation, there exists a possibility that installers may unknowingly permit the greater wire fill numbers using wire with the heavier insulation thickness. This would result in exceeding the permitted wire fills for the raceway per Chapter 9, Table 1."

In reality, this possibility would not materialize because:

1) The wire with the heavier insulation thickness would result in greater wire fill numbers is academic. This means the existing stock of the wire types THHW and THW in sizes 14-10 AWG and 8 AWG for which the insulation thickness has been reduced by the action taken on Proposal 6-47 for 1999 NEC by CMP 6 is used in an installation with proposed new fill requirement. CMP 6 took this action to harmonize requirements in the NEC with NOM 001 (Mexican Electrical Code). Typically, in the US Type THWN has replaced THW and THHW.

2) It should be noted that this change does not reduce the insulation thickness for the entire range of wire sizes for the types mentioned above. Such change may require additional markings to differentiate the same wire type when multiple insulation thicknesses are recognized for that wire type. However, neither CMP 6 or the NEC process are ready to recognize such performance requirements in the Code at the present time as evident by the actions taken for 1996 and 1999 code cycles. CMP 8 should remain assured that this proposal is not undermining those actions.

3) The suggested possibility may materialize when an existing installation is being reworked. As such, the installer needs to verify the compliance with the Code requirements when modifying an existing installation. Thus, greater wire fill (provided the rework was being carried out using an old stock of aforementioned wire types and sizes) would not materialize.

4) The suggested possibility is not feasible with new installations since the installer would comply with the requirements in the Code. Should the installer happens to use aforementioned wire types and sizes from old stock, then wire fill requirements would be computed using the actual dimensions of the wire since the Code is already reflecting new dimensions based on the action taken by CMP 6 on proposal 6-47 for 1999 NEC.
PANEL ACTION: Accept in Part.
The panel accepts recommendation 1.
The panel rejects recommendation 2.
Forward this comment to CMP-8 for information.
PANEL STATEMENT: The changes in Table 5 of Chapter 9 and in Annex C do not need to be correlated with the changes in Table 310-13 for Type THW and THHW in sizes 14 thru 10 AWG. The present dimensions of Table 5 of Chapter 9 and conduit fill data in Annex C are conservative and will not compromise safety. The recommendation to change these requirements can be addressed in future editions of the Code.

PANEL ACTION: Accept in Principle in Part.
PANEL STATEMENT: The panel accepts in principle the recommendation to delete Type AF conductors in those tables and articles under the jurisdiction of CMP-8. See panel action and statement on Comment 8-97.

The panel rejects recommendation 2 in the comment. The panel statement given by Code-Making Panel 8 on Proposal 8-458 clearly states why Proposal 8-458 should continue to be rejected and item 5 of Proposal 6-212 should be rejected. For ease of the reader the part of that statement germane to this substantiation is reproduced here.

"The panel cannot accept the recommendation to revise the tables in Appendix C to increase the wire fills. By reducing the required insulation thickness for these wire types without changing the designation, there exists a possibility that installers may unknowingly permit the greater wire fill numbers using wire with the heavier insulation thickness. This would result in exceeding the permitted wire fills for the raceway per Chapter 9, Table 1. The panel refers this action to Code-Making Panel 6 for information."

16- 405 - (Chapter 9, Table 12 (b)): Accept
SUBMITTER: Technical Correlating Committee on Signaling Systems for the Protection of Life and Property
COMMENT ON PROPOSAL NO: 16-372
RECOMMENDATION: The Technical Correlating Committee on the National Fire Alarm Code recommends that Code Panel 16 continue to reject this proposal.
SUBSTANTIATION: If an existing installation of a fire detection system that has the electrical characteristics described by this portion of Table 12(b) was moved from one location to another location within the same building, the reinstallation of the system might be considered as a new installation. If the permissive requirements of Table 12(b) are eliminated, the authority having jurisdiction might not be able to accept such a reinstallation. A similar problem might exist if an extension were made to an existing installation using spare parts on hand at a facility.
PANEL ACTION: Accept.
PANEL STATEMENT: The panel continues its position to reject Proposal 16-372.

However the panel does not agree with the substantiation provided by the submitter. The National Electrical Code provides requirements for the installation of systems in new construction or modifications to existing construction. As codes change, old requirements may not be retained or they may be replaced by newer "up to date" requirements based upon changes in technology or safety to life.

While the panel continues to reject Proposal 16-372, the continued rejection is independent of the substantiation with which we do not agree.

The submitter's substantiation suggests that if equipment is relocated within the same building it should not be considered new, and therefore the submitter implies that a new "Record of Completion," drawings of record, and all testing requirements of Chapter 7 are not required. Furthermore, implying that additional equipment can be added to an existing fire alarm system without these same requirements, simply because spare parts were on hand, may not be prudent. Spare parts are maintained on hand for maintenance and repair of the existing system, not for expanding the system. At the least, the substantiation implies that the Authority Having Jurisdiction won't know about the addition or relocated use of these detectors and therefore may not inspect them for compliance with local codes.

ANNEX A

(Log #1225)

1- 179 - (Annex A): Reject
SUBMITTER: Dann Strube, Lanesville, IN
COMMENT ON PROPOSAL NO: 1-315
RECOMMENDATION: The proposal should have been rejected.
SUBSTANTIATION: This is a companion to my comment on Proposal 1-95.

A list of related UL standards is of no real use for several reasons.

1. The list is not a full list of all UL standards used to evaluate products.
2. Many other standards are used in code enforcement, i.e., NEMA, IEC, ANSI, etc.
3. With no cross-reference from Annex A to specific code sections, the list in Annex A is no less than wasted paper filling the code with useless pages.
4. To satisfy the intent of Annex A we must include the UL White Book, UL Catalog, ANSI catalog and who knows what else.
5. The users of the NEC should be expected to understand that Section 110-3(b) requires or at least implies that compliance with other standards and instruction is required.

PANEL ACTION: Reject.
PANEL STATEMENT: Standards that form the basis for product listing to the requirements of the National Electrical Code represent a distinct and identifiable group of standards. The panel believes that listing these for reference in Annex A improves the usability of the Code. The panel agrees with the submitter's statement that some other types of industry standards and publications are also related to Code enforcement, but disagrees that these include catalogs.

1- 180 - (Annex A): Reject
SUBMITTER: Dann Strube, Lanesville, IN
COMMENT ON PROPOSAL NO: 1-80
RECOMMENDATION: Change new Article 80 to Annex XX.

Title new Annex XX Examples of Administrative and Enforcement Methods.

Add a Fine Print Note to Section 90-04 as follows:

FPN: See Annex XX for examples of administrative and enforcement methods.

Renumber the material as needed.
SUBSTANTIATION: Since this material is not part of the enforceable code, it should be in an annex. If a jurisdiction wants to adopt the material it can be adopted from an annex as well as it can from Article 80.

Located in an annex, the new material will cause less confusion than in its present location.

I am aware that the Manual of Style (MOS) Section 2.3.4.3 states that the word "shall" shall not be used in an annex. However, Annex A of the MOS is full of "shall" words. In this case, the section containing the "shall" word is used as an example. If the

new annex is an example, it seems as if it would comply with the intent and style of the MOS.

I do not object to the material and feel that it has real merit. I am not comfortable with its location.

PANEL ACTION: Reject.

PANEL STATEMENT: See panel action on Comment 1-6. The panel intends to retain Article 80 in the front of the NEC and therefore, the FPN following Section 90-4 is unnecessary.

EXPLANATION OF NEGATIVE:

PRICHARD: The list of product safety standards is not a complete list of product safety standards, but only for those that are utilized for product listing where that listing is required by the code.

(Log #1764)

1- 182 - (Annex A): Accept

SUBMITTER: Jim Pauley, Square D Company

COMMENT ON PROPOSAL NO: 1-315

RECOMMENDATION: Continue to accept the proposal with the following modifications:

1) Accept the revisions to the introductory paragraph as shown in Mr. Stauffer's affirmative comment on vote.

2) In accordance with Mr. Fiske's affirmative comment, add the following standards to the list:

- Nonincendive Electrical Equipment for Use in Class I and II, Division 2 and Class III, Divisions 1 and 2 Hazardous (Classified) Locations —— ISA S12.12

- Electrical Apparatus for Use in Class I, Zone 1 Hazardous (Classified) Locations Type of Protection - Encapsulation "m" ——— ISA S12.23.01

- Electrical Apparatus for Use in Class I, Zones 0 & 1 Hazardous (Classified) Locations: General Requirements ——— ISA 12.0.01

- Electrical Apparatus for Use in Class I, Zone 1 Hazardous (Classified) Locations Type of Protection - Increased Safety "e" ——— ISA S12.16.01

- Electrical Apparatus for Use in Class I, Zone 1 Hazardous (Classified) Locations Type of Protection - Flameproof "d" ———— ISA S12.22.01

- Electrical Apparatus for Use in Class I, Zone 1 Hazardous (Classified) Locations: Type of Protection - Powder Filling "q" ——— ISA S12.25.01

- Electrical Apparatus for Use in Class I, Zone 1 Hazardous (Classified) Locations Type of Protection - Oil-Immersion "O" ——— ISA S12.26.01

SUBSTANTIATION: Acceptance of this proposals remains critical to the integrity of the US Electrical Safety System. Although this is only an informative annex, the information contained in the Annex begins to build the necessary bridge to understanding the interactions between the parts of the system. I continue to see applications where this annex will help address questions that occur relative to the proper use of products in accordance with the NEC.

The recommended revisions are:

1) Editorial in nature via Mr. Stauffer's revisions to the introductor paragraph.

2) Seven additional standards have been added in accordance with Mr. Fiske's recommendation in his affirmative comment. The other standards from his affirmative comment are not recommended at this time because the products covered by those standards are not directly required to be listed by the present NEC rules. The formation of this annex will actually occur over a number of Code cycles. Since this is the first cycle where the annex will be introduced, the objective (as indicated in the original substantiation) was to introduce standards where the NEC had a requirement that the covered products be listed. Mr. Fiske is correct that there are other product standards that can be moved from FPN's to the Annex, but that was not the intent during this first cycle. That task of moving those standards is best undertaken by the Usability Task Group where appropriate proposals can be made to delete the FPN's and move the reference to the Annex. Also, some of the standards in Mr. Fiske are not 1st level product standards. They are standards (such as UL 1581) that are used as a portion of the evaluation, but the primary product standard (such as UL 44 or UL 83) would reference that standard. Again, the initial intent is to keep the list focused on the standard used to provide a listing for the product.

The IEC standard references have not been added because those standards are not used as stand alone documents for the certification and the proper deviations must be included. The ISA or UL standards that are included on the list have the appropriate deviations to the IEC 60079 series of document and are the primary references.

The ANSI designations were not deemed to be necessary for this list. That designation typically relies on a specific date/edition of the standard and that level of specificity was not intended for this list. The designations could certainly be added as he notes, but since the list is informative in nature, it does not increase the usefulness of the list.

PANEL ACTION: Accept.

PANEL STATEMENT: The panel does not necessarily concur with all of the substantiation.

6-235 (Table B-310-8)
6-236 (Table B-310-9)
6-237 (Table B-310-10)
All of these proposals should be accepted.
Individual panel comments seem to fall into three major categories: (1) 'Scientific ampacity' does not appear in the NEC; (2) The present definition is entirely satisfactory; (3) All NEC ampacities are scientific
My comments:
(1) These proposals were inspired by the panel's rejection, three years ago, for this very reason. Proposal 1-101 deals with the definition; the others deal with introducing the term into the text where appropriate.
(2) The present definition is great; very carefully crafted. It is not wrong, but it is inadequate. It applies only for those ampacities based strictly on thermal considerations, such as those in the tables listed above. Other ampacities are based on a multiplicity of factors (see section 310-15(b) FPN) beyond the scope of the existing definition. An objective observer would certainly conclude that the present definition is not entirely satisfactory.
(3) This is a very interesting observation. It can be reasonably stated that everything in the Code is scientific, but that obscures the point that a tremendous amount of judgment often modifies pure science. That is as it should be. In this case, what I have called scientific ampacities are pure science. They are calculated using only recognized scientific principles; nothing judgmental. They spring from the field of technology and computers. Other ampacities come from the field of wisdom, and cannot be calculated scientifically.

6-235 (Table B-310-8)
6-236 (Table B-310-9)
6-237 (Table B-310-10)
All of these proposals should be accepted.
Individual panel comments seem to fall into three major categories: (1) 'Scientific ampacity' does not appear in the NEC; (2) The present definition is entirely satisfactory; (3) All NEC ampacities are scientific
My comments:
(1) These proposals were inspired by the panel's rejection, three years ago, for this very reason. Proposal 1-101 deals with the definition; the others deal with introducing the term into the text where appropriate.
(2) The present definition is great; very carefully crafted. It is not wrong, but it is inadequate. It applies only for those ampacities

based strictly on thermal considerations, such as those in the tables listed above. Other ampacities are based on a multiplicity of factors (see section 310-15(b) FPN) beyond the scope of the existing definition. An objective observer would certainly conclude that the present definition is not entirely satisfactory.

(3) This is a very interesting observation. It can be reasonably stated that everything in the Code is scientific, but that obscures the point that a tremendous amount of judgment often modifies pure science. That is as it should be. In this case, what I have called scientific ampacities are pure science. They are calculated using only recognized scientific principles; nothing judgmental. They spring from the field of technology and computers. Other ampacities come from the field of wisdom, and cannot be calculated scientifically.

6-237 (Table B-310-10)

All of these proposals should be accepted.

Individual panel comments seem to fall into three major categories: (1) 'Scientific ampacity' does not appear in the NEC; (2) The present definition is entirely satisfactory; (3) All NEC ampacities are scientific

My comments:

(1) These proposals were inspired by the panel's rejection, three years ago, for this very reason. Proposal 1-101 deals with the definition; the others deal with introducing the term into the text where appropriate.

(2) The present definition is great; very carefully crafted. It is not wrong, but it is inadequate. It applies only for those ampacities based strictly on thermal considerations, such as those in the tables listed above. Other ampacities are based on a multiplicity of factors (see section 310-15(b) FPN) beyond the scope of the existing definition. An objective observer would certainly conclude that the present definition is not entirely satisfactory.

(3) This is a very interesting observation. It can be reasonably stated that everything in the Code is scientific, but that obscures the point that a tremendous amount of judgment often modifies pure science. That is as it should be. In this case, what I have called scientific ampacities are pure science. They are calculated using only recognized scientific principles; nothing judgmental. They spring from the field of technology and computers. Other ampacities come from the field of wisdom, and cannot be calculated scientifically.

PANEL ACTION: Reject.
PANEL STATEMENT: See panel statement on Comment 6-43.

6- 95 - (Table B-310-3): Reject
SUBMITTER: John E. Conley, Stratford, CT
COMMENT ON PROPOSAL NO: 6-231
RECOMMENDATION: Accept the proposal.
SUBSTANTIATION: These comments apply, individually, and collectively, to the following proposed actions published in the ROP for the 2002 NEC.

1-101 (100-Ampacity)
6-92 (310-15(c))
6-120 (310-60(d))
6-126 (Table 310-67)
6-127 (Table 310-68)
6-128 (Table 310-69)
6-129 (Table 310-70)
6-130 (Table 310-71)
6-131 (Table 310-72)
6-132 (Table 310-73)
6-133 (Table 310-74)
6-134 (Table 310-75)
6-135 (Table 310-76)
6-136 (Table 310-77)
6-137 (Table 310-78)
6-138 (Table 310-79)
6-139 (Table 310-80)
6-140 (Table 310-81)
6-141 (Table 310-82)
6-142 (Table 310-83)
6-143 (Table 310-84)
6-144 (Table 310-85)
6-145 (Table 310-86)
6-223 (B-310-15(b)(1))
6-226 (Table B-310-1)
6-228 (B-310-15(b)(2))
6-231 (Table B-310-3)
6-232 (Table B-310-5)
6-233 (Table B-310-6)
6-234 (Table B-310-7)
6-235 (Table B-310-8)
6-236 (Table B-310-9)
6-237 (Table B-310-10)

All of these proposals should be accepted.

Individual panel comments seem to fall into three major categories: (1) 'Scientific ampacity' does not appear in the NEC; (2) The present definition is entirely satisfactory; (3) All NEC ampacities are scientific

My comments:

(1) These proposals were inspired by the panel's rejection, three years ago, for this very reason. Proposal 1-101 deals with the definition; the others deal with introducing the term into the text where appropriate.

(2) The present definition is great; very carefully crafted. It is not wrong, but it is inadequate. It applies only for those ampacities based strictly on thermal considerations, such as those in the tables listed above. ANNEX D

(Log #1863)

2- 145 - (Appendix D, Example #D2(c)): Reject
SUBMITTER: David P. Brown, Baltimore Gas and Electric Co/EEI
COMMENT ON PROPOSAL NO: 2-315
RECOMMENDATION: This proposal should be accepted.
SUBSTANTIATION: The Panel's statement is in error. The 1999 NEC text does nothing to clarify the technical substantiation from other Code change cycles. We believe that was clearly demonstrated in our substantiation for this proposal. The issue was further clarified in Mr. Moore's negative vote comments to this proposal. There was no substantiation submitted to justify making this change in the 1999 NEC. The wording in the 2002 NEC should revert back to the wording in the 1996 NEC, which can be consistently verified using utility metered load profile data for electrically heated dwelling units.
PANEL ACTION: Reject.
PANEL STATEMENT: See panel action and statement on Comment 2-141.
NUMBER OF PANEL MEMBERS ELIGIBLE TO VOTE: 12
VOTE ON PANEL ACTION:
AFFIRMATIVE: 10
NEGATIVE: 1
ABSTENTION: 1
EXPLANATION OF NEGATIVE:
MOORE: I do not agree with the panel action or the panel statement. It is my opinion that the 1999 NEC text was not a clarification from previous cycles and was revised without adequate substantiation.

The current code allows diversification at 65 percent of nameplate rating for central electric space heating for 4 units or less. However, current code allows no diversification (100 percent of the nameplate ratings) for a system employing heat pump compressors with supplemental heating. Heat pump compressors are more efficient than electric space heating. Thus, a combination central space heating installation employing heat pump compressors with supplemental heat in simultaneous operation would have a lower demand than a pure central resistance heat system of the same size. Rating the total load of the combination unit at 65 percent would be in line with the allowed 65 percent rating for a system composed only of electric space heating.

It is also my opinion that the submitter provided the necessary substantiation for the proposal.
EXPLANATION OF ABSTENTION:
TOMAN: See my Explanation of Abstention on Comment 2-141.
